15.3 Example Scripts.....	164

1 Introduction

Cartographica™ is a Geographic Information System (GIS) package for the Macintosh. It is used to create, analyze and present geospatial data.

There are many uses of GIS and Cartographica is designed to provide many of those, with a focus on ease-of-use and data portability. To that end, the software provides import and export capabilities to a wide variety of Vector and Raster formats, as well as abilities to generate new data sets based on existing data through analysis.

1.1 Projections, Coordinate Systems, and Datum

Mapping the Earth requires a mathematical projection that enables us to view a spherical body on a two-dimensional surface. The problem of representing a sphere on a 2-D surface is that in almost all cases at least some part of the map becomes distorted due to the curvature of the Earth. To account for this problem, we have created Geographic Coordinate Systems (GCS) and datums to better represent our objects of study. Geographic Coordinate Systems contain X, Y, and Z data that provide standardized locations of objects on Earth. X coordinates generally describe longitudinal data, Y coordinates describe latitudinal data, and Z coordinates typically describe an elevation. Not all GCSs are the same once projected on a map because they are based on different datums that allow for specificity in mapping.

Geographic Coordinate Systems must be defined by a datum, which are sets of reference points on the Earth's surface. Because there are literally an infinite number of ways to view the Earth, it is critical to account for distortion in specific areas. For example, if we are studying the dispersion of moose in Alaska then we would likely not want to use the same datum in a study of kangaroo in Australia. Using specific datums allows us to get the most accurate depiction of the location that we are studying.

Generally, GIS programs such as Cartographica can quickly translate datums if they are originally projected on different or non-specific datums.

A common translation that users might encounter is if data isn't projected using the WGS 84 datum. WGS 84 or World Geodetic System (1984), is a standard datum for many GIS and GPS devices, and is the only world-wide datum. A user that brings in data collected from a GPS device and then attempts to map the data with a specific datum, might find that their map is not accurately projected.

Cartographica can account for this by translating data to an already established datum like WGS 84. We have incorporated NTv2 support to provide accurate mapping between NAD27 and NAD83.

1.2 Features

Cartographica's most basic unit of information is an Feature. A feature is a geometric container for information. Usually, we represent a feature as a point, line, polygons, or imagery. Point data is the most basic and represents a location in 2d or 3d space. Line data is the next most complex and

represents a series of points in a particular direction which are connected. Polygon (also sometimes called Area) data is the most complex data and represents a series of points which surround an area, optionally containing "holes" that cut areas out.

Multipoint

Multiline

Multiarea

1.2.1 Multi-part Features

All feature types are available in single and Multi-part features. Multi-part features provide a way to consider a group of geographical elements as a single unit. This can be helpful for representing many types of data. For example, multi-point features (multi-part points) can represent grouped locations for a particular event type or time period; multi-line features can deal with maintaining a single record for a road that is discontinuous; and multi-area features can provide a single feature to represent an archipelago. These are just examples, and you can use them in unique ways to represent your data.

1.3 Layers

In Cartographica, data is organized into Layers. A Layer consists of one type of data (point, line, area, or imagery), and contains one or more features of each type. Each of these features usually contains geospatial information (one or more sets of X,Y and possibly Z coordinates) as well as optional reference data that describes characteristics of the features in the layer. It is the attachment of the reference additional data to the geospatial information that makes a GIS like Cartographica so powerful. By using the geospatial data, correlations can be made between information in the reference data, leading to informative maps and insightful data analysis.

Layers

Composite

Layers Alone and Compositd

1.3.1 Types of Layers

Cartographica uses a number of different types of layers to represent data in MapSet. Each one can be enabled or disabled, and can have various attributes manipulated, as appropriate. A basic description of each is included here.

Layer	
Vector	Vector layers are comprised of lines, points, or polygons. There are many tools that can use the Vector layers for data analysis and manipulation. Common uses are representing discrete locations (points), roads or rivers (lines), and areas (polygons).
Raster	Raster layers are comprised of a grid of individual data cells that can be interpreted many ways. Common uses are representing height or depth data, containing data for frequency or counts of incidents in specific locations, or providing color or false color data from

Layer	
	satellite imagery. There are specialized tools in Cartographica to process Raster data, including computing topography, and merging with similar data.
Grid	Grid layers provide geospatial context to other layers. When added to maps, they render a grid of lines demarcating areas in the Map or Layer reference system.
Analysis	Analysis layers are specialized Raster layers. They contain not only the resultant raster data from an analysis, but also the parameters used to make that analysis.

Layer Descriptions

2 Getting Started with Cartographica

2.1 Installing Cartographica

Cartographica is delivered over the internet in a standard Macintosh disk image, which is just a way to package Macintosh programs and files so that they are not harmed during transport across the Internet.

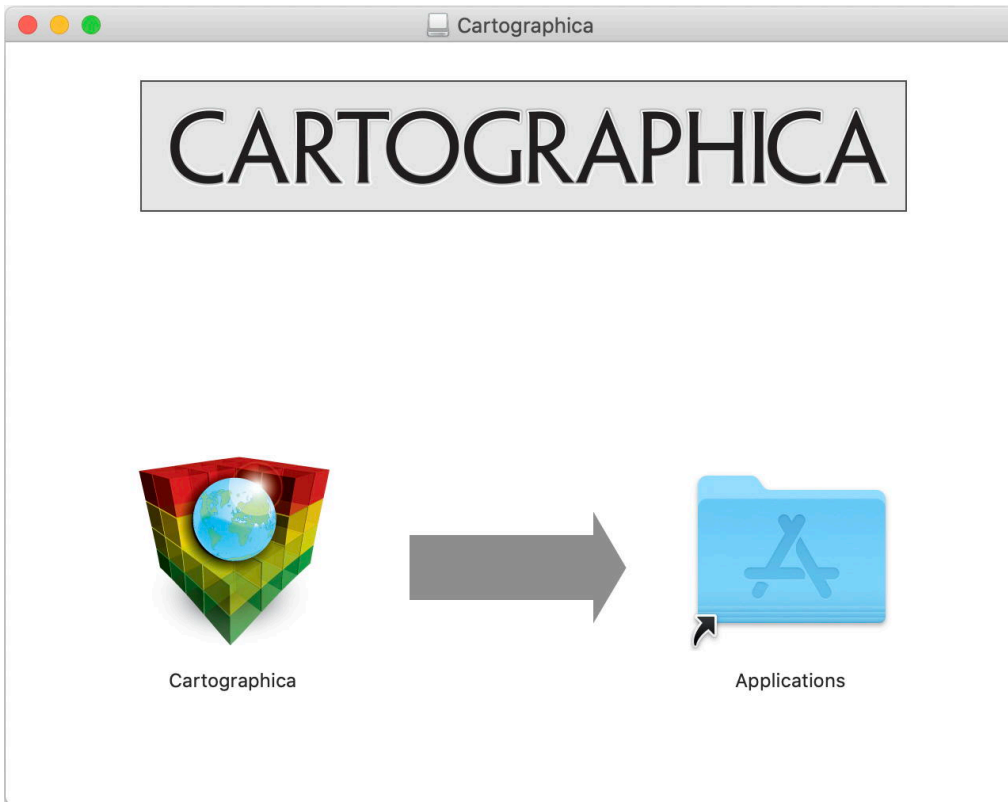

For those who are not familiar with this kind of software delivery, it can be a bit confusing. The disk image acts just like a CD inserted into your Macintosh, but without the physical media. Once the disk image shows up on your computer, the contents only stay there until you Eject the disk image from the Finder.

Although it is possible to run Cartographica from the disk image, it is not suggested, as it can become confusing to have to reload the disk image (and re-accept the license agreement) each time you run the program.

The Cartographica disk image contains the license agreement and may contain additional information along with the program itself.

2.1.1 Installing Cartographica from the disk image

1. Locate the Cartographica disk image in the Finder
If you have just downloaded it from the MacGIS.com site, the disk image will be inside of your default download folder.
2. Double-click on the disk image file to open it
The Cartographica license agreement window will appear. Read through the agreement until you are satisfied that we aren't doing anything bad.
3. Click **Accept** to continue
The contents of the Cartographica disk image should now be visible in the Finder.

Cartographica Disk Image

4. Drag the **Cartographica** program icon from the disk image into your **Applications** folder

 Although you can theoretically place Cartographica anywhere you would like on your computer, recent versions of macOS make it most convenient to place Applications in the Applications folder, and ClueTrust recommends doing so.

Cartographica is now installed and ready to run.

5. Choose **Go > Applications** in the Finder to open the Applications folder.
6. Optionally, drag the Cartographica icon from the Applications folder to the Dock if you want to be able to access Cartographica quickly from the dock.
7. Double-click on **Cartographica** in the **Applications** folder or click on **Cartographica** in the dock to get started.

2.2 Updating Cartographica

Cartographica has a built-in update service that helps to make sure that you have the most recent updates to the software. When you run Cartographica for the second time, you will be asked if you would like to let Cartographica check for updates. We strongly suggest that you allow Cartographica to do this check as it will keep you informed of any important bug fixes and feature additions.

You can always opt in or out of the automatic update process later by changing your update preferences. Even if you opt out of the auto-update process, you can still use the updating mechanism in Cartographica to check for updates manually.

2.2.1 Changing your auto-update preferences

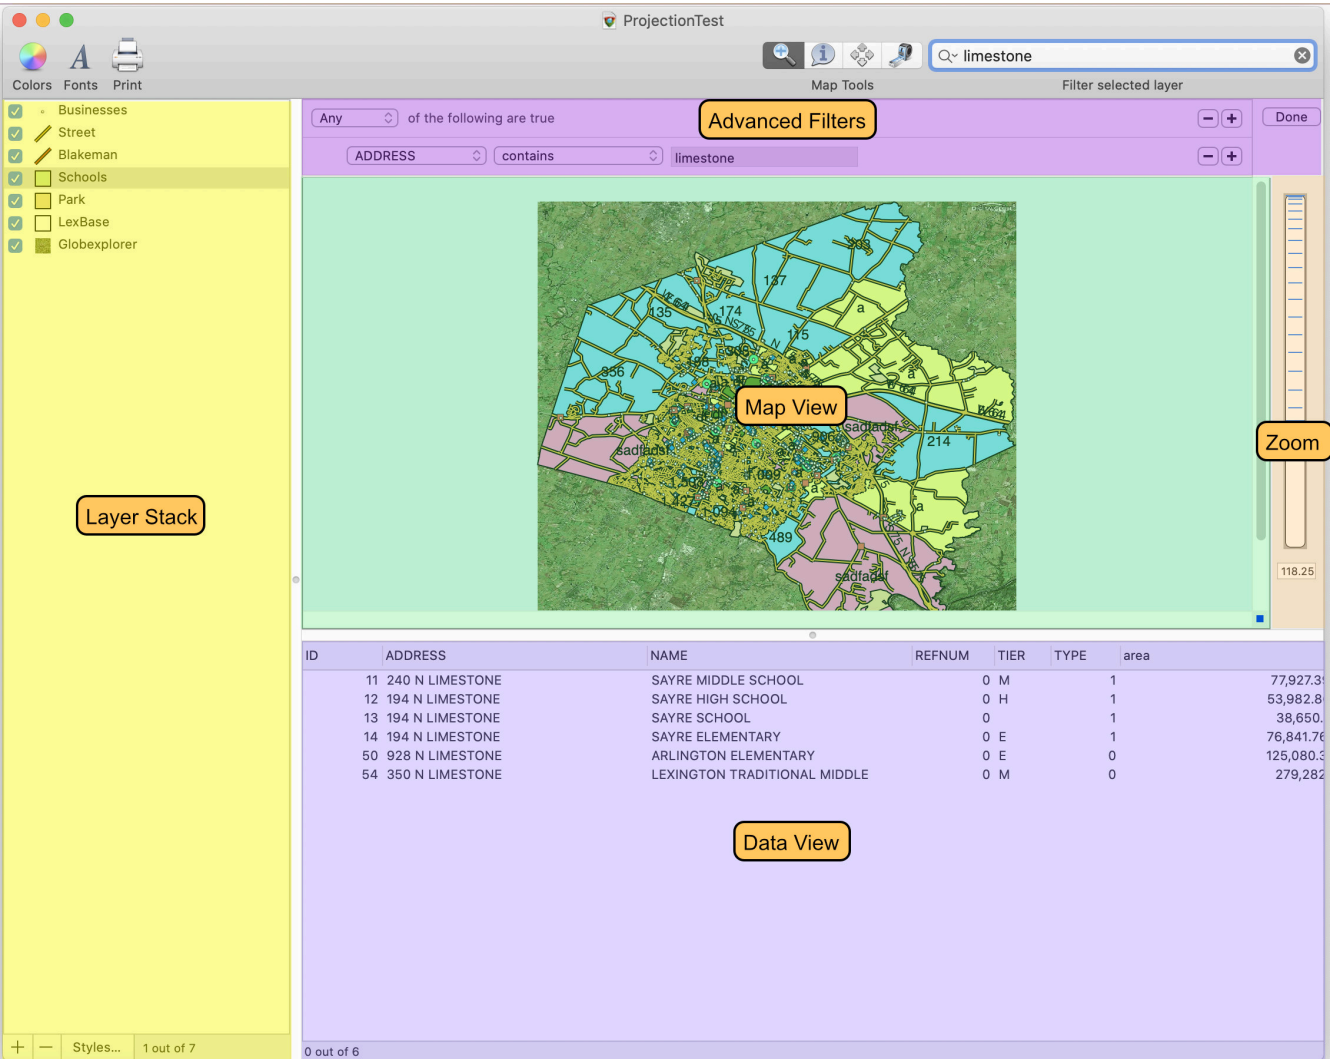

1. Choose **Cartographica > Preferences...** to bring up the **Cartographica Preferences** window
2. Check **Automatically Check for Updates** to enable the auto-updater and uncheck it to disable the feature.
3. Advanced users may wish to subscribe to the Development or Beta versions of the software in order to help test future features in Cartographica. Although it is suggested that most people leave the update setting at **Release**, you can change it to **Beta** or **Development** if you are instructed to do so.
4. Optionally check **Sends System Profile Information** if you want to help out ClueTrust by sending along some basic (non-identifying) statistical data about your computer when you check for updates.

Manually updating Cartographica

1. Choose **Cartographica > Check for Updates...**
If there is a new version of Cartographica available, you will be presented with information about changes in the updated software and given the option to install it or to defer until later.
2. Click **Install Update** to begin the update process
Cartographica will download the new version while you work and then prompt you later to install the new copy.
3. Click **Install and Relaunch** to shut down Cartographica, install the new version, and restart the program.
Once Cartographica restarts, you're ready to use the new version.

2.3 Interface Overview

When you initially open a Cartographica map the Map Window appears. [Main Cartographica Window](#) shows that window with a map already loaded in it. This window is the centerpiece of Cartographica and where most of the work is done. In the figure we have shaded various sections of the window for purposes of explaining the layout and function of each of the sections.

Main Cartographica Window

Toolbar	<p>The Toolbar at the top of the window provides access to often-used functions in Cartographica.</p> <p>As with all toolbars on the Macintosh, it is optional and may be hidden, resized, or changed by using the Toolbar Button in the upper right corner of the window or View > Customize Toolbar...</p>
Layer Stack	<p>The layer stack shows the list of all layers in the map document and provides an easy way to re-order layers, change styles, and show or hide individual layers. The selection in the Layer Stack provides guidance to the Map View and Data View as to which data is selectable.</p>

	 What do the little triangles mean in the layer stack? You may see a warning triangle in the right side of the Layer Stack. If this happens, click on the triangle to find out more about the problem is with the layer, and potential fixes. The most common cause of the warning triangle is a layer that has no valid CRS.
Map View	The powerhouse of Cartographica, the Map View shows your geospatial data in context with all of the visible layers.
Data View	The Data View is used to show and edit data for the vector layer selected in the Layer Stack.
Zoom	The Zoom area is used to control and display zoom information about the Map View. The Zoom Dial can be used like a slider to zoom out (slide up) or zoom in (slide down). Below the Zoom Dial is the Zoom Factor Box which shows the percentage zoom in effect right now. Typing a new value in this box will change the zoom level directly.
Advanced Filters	The Advanced Filters area is not always visible, but once you have started performing a filter operation (using the Filter box in the Toolbar), it will pop into view. Advanced filters provides for boolean operations so that you can search and filter on more than one variable at a time.

2.3.1 Utility Windows

Cartographica uses Utility Windows (sometimes called palettes) that float above other windows in order to provide access to more information about the current context. The content of these windows is synchronized to the current Map Window, so if you have more than one Map open, they will change when you switch back and forth between the Map Windows. Each of the Utility Windows is accessible via the **Window** menu.

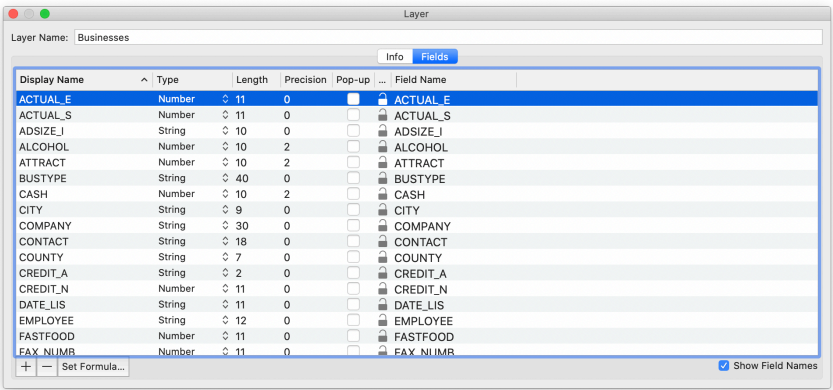

Measurements	The Measurements Window provides information about the position directly underneath the cursor or the current selection when dragging. See for details on how to bring up and use the Measurement window.
--------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Measurements Window

Layer Info

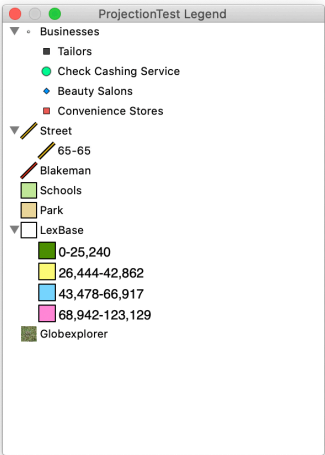

The Layer Info Window provides information about the layer currently selected in the Layer Stack. Changes made in this window affect the data in the selected layer.

Layer Info Window

Legend

The Legend Window provides a quick reference to all of the layer styles in the current Map.

Legend Window

Image Viewer

The Image Viewer Window provides an enhanced view of any pictures referenced by a feature using the Picture item in the Style window.

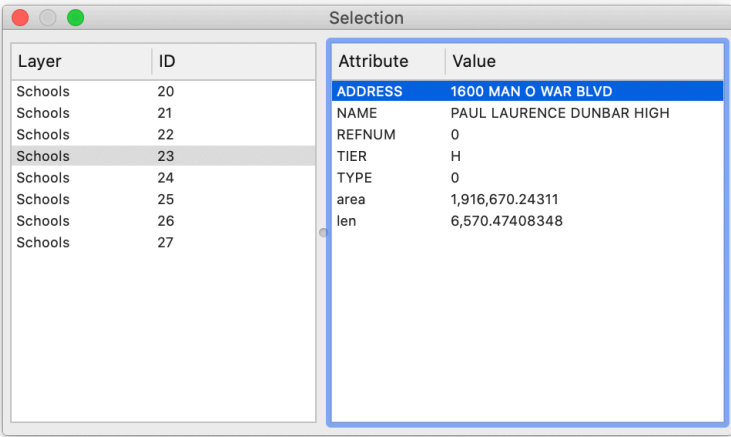

Image Viewer Window

Selection Info

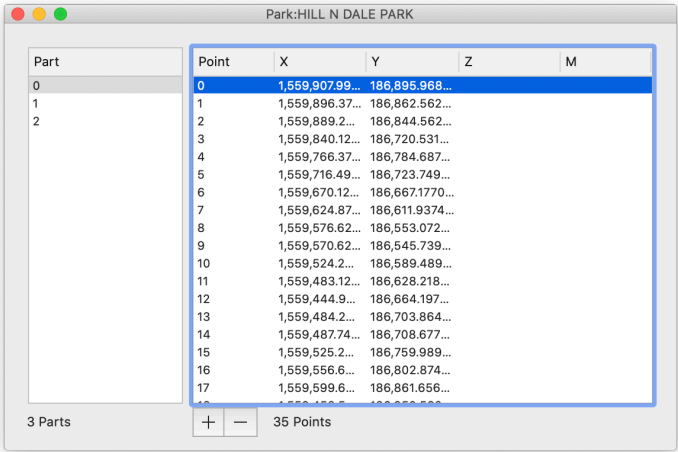

The Selection Info Window provides a concise view of all selected objects. On the left is a list of all features currently selected and the layer that they belong to. On the right is the information about the selected feature.

Selection Info Window

Point Data

The Point Data Window provides a detailed of all points in geometry of the selected feature. On the left is a list of all parts (all geometries have at least one part if they have any points). On the right is a list of all points in that part. Point information may be edited manually in this window. It is important to remember that all coordinates in this window are in the layer's coordinate system, not in the map's coordinate system.

Point Data Window

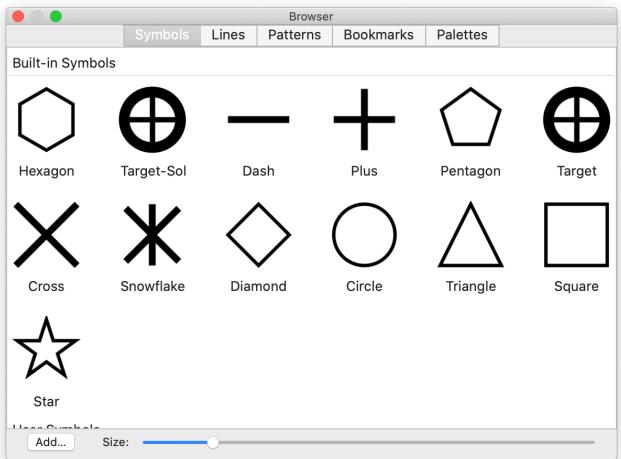

Selection Summary	<p>The Selection Summary Window provides a statistical summary of a single column of the selected objects. The Column drop-down determines which column's data is summarized for the selection.</p>  <p>Selection Summary Window</p>
-------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

2.3.2 The Uber Browser

The following items are shown inside of the Uber Browser window. The Uber Browser provides a single location to choose from built-in and user-saved symbols, palettes, bookmarks, and other items that are used across all maps. Since Cartographica supports drag-and-drop to do many things, it serves as the starting point for dragging into other windows. Each tab in the Uber Browser will be described separately in this document, as the tabs themselves are where the content lies, however each is accessed through the Uber Browser, which can be shown by using **Window > Show Uber Browser**.

Each tab is described below:

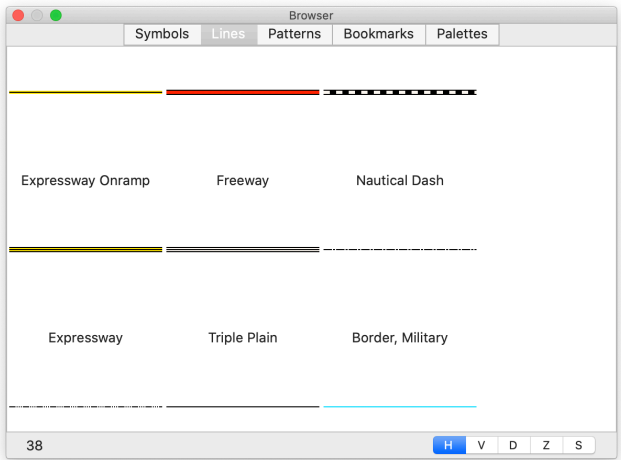

Symbols	<p>The Symbols tab provides access to all built-in and user-defined symbols in Cartographica, for use when changing styles for point layers. For more information, see Point Styles</p>
---------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Symbol Tab

Lines

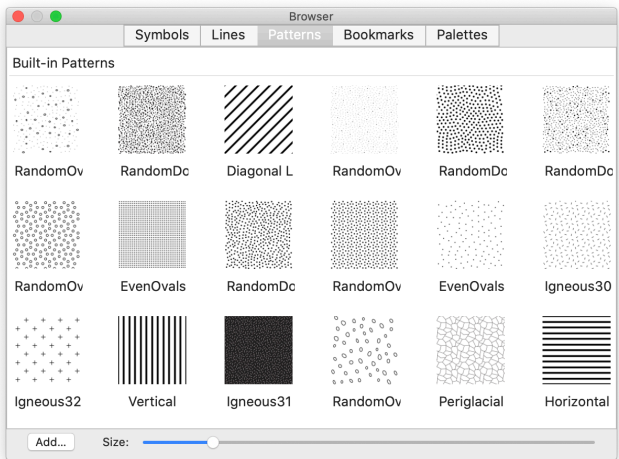

The Lines tab provides access to all built-in line styles in Cartographica, for use when changing styles for line layers and outlines in polygon layers. For more information, see [Polygon Styles](#).

Lines Tab

Patterns

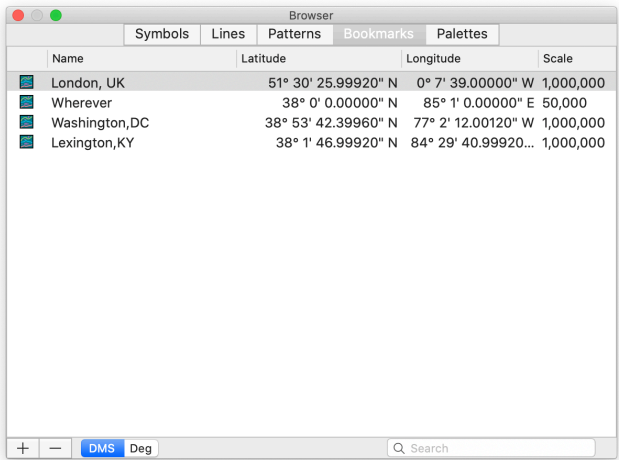

The Patterns tab provides access to all built-in and user-defined pattern swatches in Cartographica, for use when changing styles for polygon layers. For more information, see [Polygon Styles](#).

Patterns Tab

Bookmarks

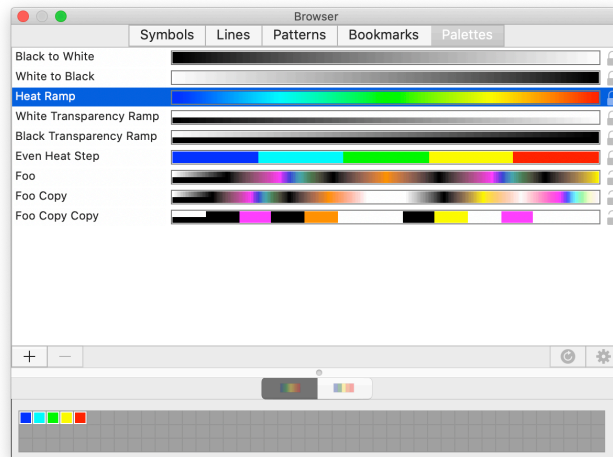

The Bookmarks tab provides access to all built-in and user-defined geographical bookmarks in Cartographica, for use when navigating and exploring in the map window.

Bookmarks Tab

Palettes

The Palettes tab provides access to built-in and user-defined color palettes that Cartographica can use for vector and raster data. This window provides for selection of palettes as well as creating and editing them.

**Palettes Tab**

2.4 Drag and Drop throughout Cartographica

Drag and drop is used extensively throughout Cartographica where it is reasonable. Usually it provides a shortcut to some functionality elsewhere in the program's menus and windows. A few of these drag and drop shortcuts are elaborated here, but if it makes logical sense to drag and drop something it will most likely work.

- Drop vector or raster files on the map window to import them.
- Drop picture files that contain GPS Location data the Map View and they'll be plotted in a new layer on the map.
- Drag layers to reorder them in the layer stack.
- Drop one layer on another to copy the styles.
- Drop a color swatch from the color picker onto the map background and change the background.
- Drag a layer from one map window to another in order to create a new copy of that layer in the map you drop it on.
- Drop a map icon (grabbed from the title bar) into a Map Layout document to add a map copy there.
- Drop color maps onto analysis layers to change the color map.

2.5 Undo everywhere

Since one of Cartographica's key goals is to help you understand your data better, we believe it is important to be able to quickly experiment with new ways of looking at your data. To help with this, Cartographica is replete with undo and redo capabilities, making it possible to experiment with new ideas to your heart's content without having to fear that you'll do something you can't undo.

3 Importing Data into Cartographica

3.1 Overview

Cartographica is commonly used to provide visual interpretations and facilitate analysis of geospatial data. Most data that is analyzed in Cartographica is not created or produced internally. Instead, users typically add data into the maps that have been previously obtained from entities like government agencies or private businesses.

Cartographica imports data from many sources. Using algorithms created by the ClueTrust team and by the folks who create, maintain, and contribute to Geospatial Data Abstraction Library (GDAL), Cartographica is able to bring in data from an enormous number of sources, including (but not limited to):

- ESRI® Shape Files
- MapInfo® MAP Files
- USGS DEM and DRG files
- Ordnance Survey and GML files
- ESRI Personal Geodatabase
- GPX files
- KML files
- ESRI File Geodatabase

The types of files you will use as source data will vary depending upon what you have available and what specific needs you have. The general kinds of data that Cartographica can import are:

Vector Files	Files that contain referenced data in numeric form that can be scaled up to the resolution of the data. Vector data includes data such as points, lines, and polygons.
Raster Files	Files that contain picture information (such as an orthophoto) or data sampled at a specific resolution as point sources. Raster Data includes data such as pictures or satellite images, as well as sample grids and height or depth data.
Text Files (or Table Data)	Text files can be used to bring in simple geospatial data (such as points) or to merge in adjunct information, and usually contain lists of values (or fields). Table data include comma separated values (csv) and tab separated values (tsv). Text/Table import supports a variety of character sets, including UTF-8, WindowsLatin1, and others. If you are using a non UTF-8 character set, it's best to set that when opening the file.

GPS Data	GPS Devices provide location information sampled at a particular point in time. For most purposes, these are waypoints (point sources marked by the GPS User) and tracks (timestamped record of the device's travels).
Database Information	Databases can contain many of the types of data already described above. Although they usually most similarly resemble Text Files (fields of data and possibly simple geospatial data), some database formats contain complex geometry.

Common File Types

For many applications, a single Cartographica Map Set will contain multiple layers loaded from more than one type of file or other data source. For example, vector data is often used with an underlying raster image in order to show it in the context of an aerial photo.

With Version 1.2 of Cartographica, we have introduced the ability to use dynamic maps as well as the static maps that we have described so far. These can take on a number of different forms, including vector data and raster imagery and can come from a variety of sources.

Bing™ Maps	Bing Maps provides images for use as background maps in Cartographica (and other programs as well as many web sites). The images available include satellite imagery, roads, and a hybrid combination of the two. Access to the Bing data requires an active support license for Cartographica.
OpenStreetMap	OpenStreetMap is a service and an informal protocol. Although the original OpenStreetMap is a service run from the UK which provides street-level map data which has been put together on a volunteer basis around the world, the URL pattern used by OpenStreetMap has now become an ad hoc standard and is also used by other providers. Cartographica can support any tiled data source that uses the OpenStreetMap URL pattern.
Web Map Servers	Web Map Servers are servers that use the WMS protocol, defined by the Open Geospatial Consortium (OGC). This protocol is widely used in private and public systems and a growing amount of data is available using it. WMS data is by nature raster data, meaning that it carries no attributes with it. It is most commonly used as background imagery or to offload complex overlay tasks to a server so that clients do not need to merge multiple layers.
Web Feature Servers	Web Feature Servers are servers that use the WFS protocol, also defined by the OGC. This protocol is widely used in private and public systems and a growing amount of data is available using it. Unlike WMS, WFS serves data which is, by nature, Features and therefore vector. Data from these types of services may be used in analysis and more flexibly understood.

Server-Based Formats

3.2 Importing Vector Files

Vector files contain geospatial information and often have accompanying reference data that describes the data in the files.

3.2.1 Importing Vector Files

1. Choose **File > Import Vector Data....**
The standard file chooser will come up
2. Select the vector file to import and click **OK**
If you have more than one file to import, you can either select multiple items during this import.
The projection of the map will be set by the first layer added, and projections of each file will be recorded as loaded to make sure each layer is reprojected correctly.

 Vector imports are quite straightforward and usually do not require any additional decision making, but in the event that your data is in a non-standard character format, you can override the automatic character format detection and select it explicitly. Data loaded from these files is inserted into the Cartographica system as points, lines, or polygons (as appropriate) and any per-feature data is added as necessary. These options are hidden until you access them with the **Options** button in the import window.

3. Once you have imported the data, choose **Layer > Set Layer Projection...** to confirm that the coordinate system of the data is accurately selected

3.2.2 Characters and Encodings

For shapefiles, Cartographica attempts to figure out what kind of encodings are used in the files by first checking for a ".cpg" file (which will be written by ESRI's products when attempting to write out files that don't conform to specifications in the DBF format), then looking at the LDID inside of the ".dbf" file itself.

If that fails, the presumption is that the data is in ISO Latin 1, which is the default for older files. We have confirmed success working with UTF-8 and many other character sets, but since not all characters are represented in the schemes other than UTF-8, there is the potential for losing some data when exporting to other character formats.

In the case of GML and KML, the imported data is presumed to be Unicode UTF-8 (unless specified otherwise in the file itself, since there exist ways to do that in these XML-based formats). Other file types may use specific characters set in the import window.

3.3 Importing Raster Data

Raster files contain data whose form is that of samples in some form of matrix. The most common example of this kind of file is an orthophoto image file (such as a TIFF or JPEG). In these files, the data provided are color information and the matrix is the frame of the picture. Cartographica supports the efficient use of large Raster files (tested up to 7GB).

Raster files can take on many forms. Some of the more common forms you may want to import include:

- GeoTIFF files consisting of geo-referenced picture or grid data
- USGS DRG files consisting of georeferenced picture data
- DEM (Digital Elevation Model) Files contain elevation data in a point matrix
- Orthophotos - aerial photos that are geometrically corrected to make the scale uniform

Importing Raster Files

1. Choose **File > Import Raster Data**.
2. Select the file to import and click Open.
If you have more than one file to import, you may select multiple items during this import.
Some raster data is not georeferenced and may not be positioned correctly on the map. See to solve this problem.
3. Once you have imported the data, choose **Layer > Set Layer Projection** to confirm that the coordinate system of the data is accurately represented (including Datum and Projection).
Once the data is imported, you can use the dedicated layer style window for raster layers to display and change the color palette applied to the raster data. This is particularly useful for files such as DEM, in which samples are made up of floating-point or integer information instead of colors. In addition, by using the **Tools > Merge Selected Raster Layers** you can place more than one dataset in the same layer, forcing them all to use the same palette over the same range. In automatic mode, the range is the range of all datasets in the layer. In manual mode, the range is determined by the user.

3.4 Importing Text Files and Table Data

Cartographica can import text files that contain tables as geospatial and data sources. Cartographica can use text files (either CSV, TSV or DBF) to provide three different types of data:

Coordinate data	Coordinate data contains either X,Y coordinates or latitude and longitude.
Grid data	Grid data contains locations using a specific grid system.
Address data	Address data contains postal addresses.
Tabular data	Tabular data contains no geospatial information.

Because there is a great variety of sources and types of data which originate in non-geospatial files, Cartographica has a few mechanisms that are used consistently in many of our importing systems.

3.4.1 The Import Map

Cartographica uses the Import Map when [importing tabular data](#) and [acquiring database data](#). It serves two purposes: first to determine how to associate new data with an existing or new layer, and second, to determine how to relate the imported data geospatially to the rest of the data in the map.

Import Map Window

The left side of the Import Map window is used to define the relationship between fields within the file or database that is being imported and the layer that they are being imported into. The meaning of each column is detailed here.

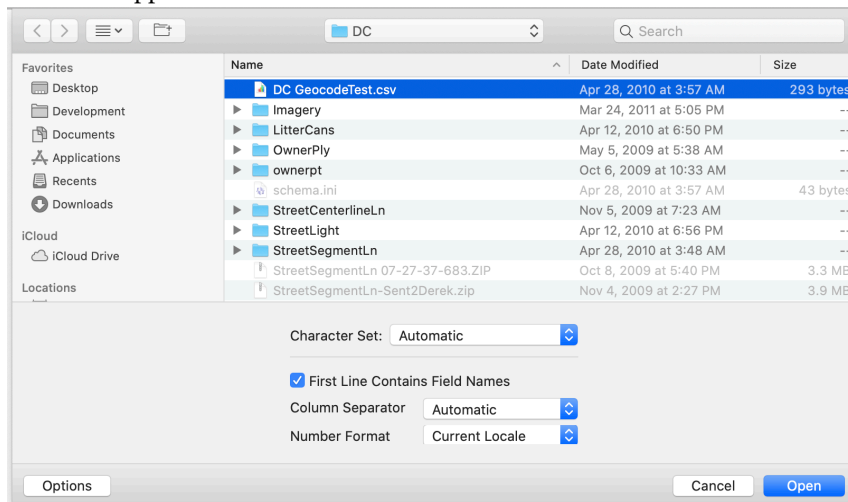

Field	Purpose
Field Name	The name of the field being imported. Based either on the initial line of the file or the database source that the data is coming from.
Type	The kind of data being imported (String, Number, Date, etc). This is determined either directly from the import source or by heuristic. If necessary, the type information may be overridden by choosing a different type in the Type menu.

Field	Purpose
Map To	Determines which column this field will map to in the resultant layer. When set to New Column, a new column with this name will be added to the table. Special values for geocoding and Coordinate import are also available. Existing fields are listed if the target layer is not new. - Do Not Import - tells Cartographica not to import this field at all.
Key	The Key field is only used for the Join style of importing, and we be detailed in section Joining Non-Geospatial Data . When the Key box is checked, the corresponding relationship between the imported field and the Map To field is used to determine which feature to associate a row from the data file with.

3.4.2 Importing data from Text and DBF files

Importing files containing coordinate data

1. Choose **File > Import Table Data....**
The [import table file chooser](#) appears.

Import Table File Chooser

This chooser is a standard file chooser with a few additional options to control how the imported text is interpreted. The character set may be chosen, overriding the default character set in the file. For text files, you may also tell Cartographica to consider the first line of the file to contain field names (the default), and designate the column separator and number format.

2. Select the location of the text or table file you want to import and click **Open**.
The **Import Map** window appears and describes the format of the file and requests that you determine how it should interpret the data as it is read.
3. Using **Target Layer** select an existing layer to append the data to, or choose **New Layer**.
4. Choose **Coordinates** from the right hand set of tabs in the window. This will enable coordinate import mode. Because you are in coordinate import mode, the choices in your **Map To** column include **X (or longitude)**, **Y (or**

latitude), **Z (or altitude)** and **M (or time)**, along with the standard options of - **Do Not Import** -, **New Column**, and any columns that exist in your selected target layer.

5. Using the **Import Map** (as described in [The Import Map](#), map the incoming data fields to your selected layer, making sure that you map at least one column to the X and Y coordinates. Without both of these, Cartographica cannot place the data on the map.
6. Click **Import** to import your data into the map.
Cartographica will read the data from the file, interpret the columns to the best of its abilities and store them into the requested layer.
7. Once you have imported the data, choose **Layer > Set Layer Projection...** to confirm that the coordinate system of the data is accurately represented.

Importing files containing grid reference data

1. Choose **File > Import Table Data....**
The [import table file chooser](#) appears.
2. Select the location of the text or table file you want to import and click **Open**.
The **Import Map** window appears and describes the format of the file and requests that you determine how it should interpret the data as it is read.
3. Using **Target Layer** select an existing layer to append the data to, or choose **New Layer**.
4. Choose **Grid** from the right hand set of tabs in the window. This will enable grid reference import mode.
Because you are in grid reference import mode, the choices in your **Map To** column include **Reference**, **Z (or altitude)** and **M (or time)**, along with the standard options of - **Do Not Import** -, **New Column**, and any columns that exist in your selected target layer.
5. Choose the desired grid from the **Grid** pop-up menu. Each grid is associated with a specific reference system and CRS.
Check the **Use Polygons** box if you want polygons instead of points for references (this is more useful if you have large grid references that cover entire areas). If unchecked, Cartographica will choose the point in the lower-left corner of the grid reference.
Check the **Include Diagnostics** box if you want Cartographica to include any grid size information and any errors (note: these will only show up if you also check **Import Non-Matching data**).
6. Using the **Import Map** (as described in [The Import Map](#), map the incoming data fields to your selected layer, making sure that you map at least one column to the Reference. Without that column, Cartographica cannot place the data on the map.
7. Click **Import** to import your data into the map.
Cartographica will read the data from the file, interpret the columns to the best of its abilities and store them into the requested layer.
8. Once you have imported the data, choose **Layer > Set Layer Projection...** to confirm that the coordinate system of the data is accurately represented.

Importing files containing address data

Before importing address data, the geocoder must be appropriately configured. This is an easy process, explained in [Geocoding Addresses](#).

1. Choose **File > Import Table Data....**
The [import table file chooser](#) appears.

2. Select the location of the text or table file you want to import and click **Open**.
The **Import Map** window appears and describes the format of the file and requests that you determine how it should interpret the data as it is read.
3. Using **Target Layer** select an existing layer to append the data to, or choose **New Layer**.
4. Choose **Geocode** from the right hand set of tabs in the window. This will enable address geocoding mode.
Because you are in address geocoding mode, the choices in your **Map To** column include **Address 1** through **Address 4**, **City**, **State**, **ZIP**, **ZIP+4**, and **Country** along with the standard options of - **Do Not Import** -, **New Column**, and any columns that exist in your selected target layer.
5. Check the **Include Diagnostics** box if you want Cartographica to include additional diagnostic and position information obtained through geocoding.
6. Using the Import Map (as described in [The Import Map](#), map the incoming data fields to your selected layer, making sure that you map at least one column to Address 1. If it is the only column specified, then it will be presumed to have a full address in it.
7. If necessary, fill in one or more of the **City**, **State**, or **Country** boxes in the right pane. These act as defaults for the geocoder in the event that there are no columns that match. Often city data is delivered with only the street portion of the address, and these fields can be used to limit the search to that particular city.
8. Click **Import** to import your data into the map.
Cartographica will read the data from the file, interpret the columns to the best of its abilities using the geocoding specifications and store them into the requested layer.
9. Once you have imported the data, choose **Layer > Set Layer Projection...** to confirm that the coordinate system of the data is accurately represented.

3.5 Acquiring Database Data

Acquiring database information works similarly to importing data from files, except that instead of reading the data from a data file, it is read from a database. By using Open Database Connectivity (ODBC) Cartographica is compatible with a wide variety of file formats and database systems (including, but not limited to: Filemaker Pro, Oracle, MySQL, PostgreSQL, and many others). We test against [Actual Technologies ODBC drivers](#) for the macOS, as they are the strongest player in the market.

As with importing tables, Cartographica uses the [The Import Map](#) in order to map incoming data to coordinates or addresses.

 Due to the nature of the ODBC drivers on the Macintosh, there are some compatibility issues with certain combinations of data and drivers. If you plan to import data with ODBC, please visit the [ClueTrust Knowledgebase](#) and read the article on ODBC.

 Cartographica currently does not support using external database as active storage for geospatial data. As such, we support database imports for address, coordinate, and grid data, and can Join geospatial and non-geospatial data, however we do not support the varied methods for storing geospatial data directly in databases.

The trickiest part about reading data from a database using ODBC is setting up the ODBC connection on the system. Although that task is beyond the scope of this manual, there are good documents available for doing this from the vendors of the connection software. In particular, if you are using FileMake Pro, they have a good site, and Actual Technologies provides excellent support for their crop of 64-bit drivers.

As with tables, database data can be interpreted in a variety of ways when it is imported to the system. Coordinate imports, grid reference imports, geocoding, and joins are all available for data from databases.

3.5.1 Acquiring coordinate data from a database

1. Choose **File > Acquire Database Data...**

The **Data Source** window appears.

Data Source Window

2. Select a **Data Source** and enter a **User Name** and **Password** if required.
3. Click **Connect** and Cartographica will retrieve and present a list of tables.
4. Choose a table from the **Table** menu to import and click **Select**.
5. Using **Target Layer** select an existing layer to append the data to, or choose **New Layer**.
6. Choose **Coordinates** from the right hand set of tabs in the window. This will enable coordinate import mode. Because you are in coordinate import mode, the choices in your **Map To** column include **X (or longitude)**, **Y (or latitude)**, **Z (or altitude)** and **M (or time)** along with the standard options of - **Do Not Import** -, **New Column**, and any columns that exist in your selected target layer.
7. Refer to for details on how to map fields with the **Import Map** window.
8. Once you have imported the data, choose **Layer > Set Layer Projection** to confirm that the coordinate system of the data is accurately represented.

Acquiring address data from a database

1. Choose **File > Acquire Database Data...**
The **Data Source** window appears.
2. Select a **Data Source** and enter a **User Name** and **Password** if required.
3. Click **Connect** and Cartographica will retrieve and present a list of tables.

4. Choose a table from the **Table** menu to import and click **Select**.
5. Using **Target Layer** select an existing layer to append the data to, or choose **New Layer**.
6. Choose **Geocode** from the right hand set of tabs in the window. This will enable address geocoding mode.
7. Because you are in address geocoding mode, the choices in your **Map To** column include **Address 1** through **Address 4**, **City**, **State**, **ZIP**, **ZIP+4**, and **Country** along with the standard options of - **Do Not Import** -, **New Column**, and any columns that exist in your selected target layer.
8. At this point, you will be presented with an **Import Map** window. Please refer to [The Import Map](#) for details on how to use the **Import Map** window.
9. Refer to for details on how to map fields with the **Import Map** window.
10. Once you have imported the data, choose **Layer > Set Layer Projection** to confirm that the coordinate system of the data is accurately represented.

3.6 Joining Non-Geospatial Data

At times it may be necessary to add data to an existing layer by cross-referencing that data with another table. Cartographica does this by matching columns in an existing layer with data from a file and adding the new data to features which match. This operation is called a join in database parlance and by some GIS packages.

To join data, use the **Map To** column to specify the destination column for the imported data (or **New Column** if you want to add a new column for the imported data). Matching criteria is specified by checking the **Key** box next to a column. Checking more than one **Key** box will only add the data when all **Key** fields match.

As an example, here is some existing Polygonal data (Example Data A) for three Counties that exist in two different States:

County Name	State Name	Area (Sq KM)
Floyd	Kentucky	1,020
Loudon	Virginia	1,347
Floyd	Virginia	989

Example Data A - Original Data

 Note that Floyd counties exist in both states

Here is the data you want to join with the above data (Example Data B):

County Name	State Name	1990 Census Population	2000 Census Population
Barren	Kentucky	38,033	30,033

County Name	State Name	1990 Census Population	2000 Census Population
Adair	Iowa	8,243	8,244
Floyd	Kentucky	42,441	40,441
Fairfax	Virginia	1,077,000	1,099,000
Loudon	Virginia	169,599	269,599

Example Data B

Here is the result of performing the Join of Example Data B to Example Data A using County Name and State Name columns as keys:

County Name	State Name	Area	1990 Census Population	2000 Census Population
Floyd	Kentucky	1,020	42,441	40,441
Loudon	Virginia	1,347	169,599	269,599
Floyd	Virginia	989		

Result of original then joined by County Name and State Name as key

In the final table, the extraneous data supplied in Example Data B \ (Adair, Iowa and Barren, Kentucky) which did not match entries in the existing table is discarded. Further, the lack of data about Floyd, Virginia resulted in empty columns.

Note that if only the County Name was used as a key and all other columns were matched, then both Floyd counties \ (the one in Virginia and the one in Kentucky would have values set in all columns, including replacing the State Name column. However, the explicit use of a multiple key means that Cartographica will only consider a match when all elements match.

County Name	State Name	Area	1990 Census Population
Floyd	Kentucky	1,020	42,441
Loudon	Virginia	1,347	169,599
Floyd	Kentucky	989	42,441

Result of original joined with just County Name key

In the case that a feature in the layer matches multiple rows in the joined table, each row from the table will replace columns in succession, resulting in the final feature data matching the last matching row in the table.

3.7 Acquiring GPS Data

Cartographica supports loading data directly into a mapset from a wide variety of GPS receivers. Imported data is represented as follows:

Tracks	Loaded as lines with each line containing a full track and missing data being represented by discontinuous lines. Altitude is used as the Z coordinate. Time is used as the M coordinate.
Waypoints	Loaded as individual points, with each point containing as much data as is available, Z coordinates are set to altitude if available.
Routes	Loaded as continuous lines with each waypoint represented by a single point in the line. Altitude is loaded in the Z coordinate if available. M is ignored.

Imported Data

Because of ClueTrust's long-standing efforts in Macintosh GPS connectivity (the free LoadMyTracks software has been given away by ClueTrust since 2006), Cartographica supports a large number of GPS devices for import. Please visit our support site for a detailed listing, but the classes of device and their manufacturers are listed in along with any special considerations for each type.

GPS Type	Special Considerations	Import Options
Garmin USB	Make sure that your Garmin USB GPS is plugged in and turned on before clicking Acquire.	Tracks, Waypoints, Routes
Garmin Serial	Select the serial port that your Garmin GPS is connected to and click Acquire.	Tracks, Waypoints, Routes
Garmin Storage	Make sure that your Garmin Storage GPS is plugged in and turned on before clicking Acquire.	Tracks, Waypoints, Routes
GlobalSat DG-100	Select the serial port that your GlobalSat GPS is connected to and click Acquire.	Tracks
GlobalSat GH-615	Select the serial port that your GlobalSat GPS is connected to, activate Data Link to PC mode on the GPS and click Acquire.	Tracks, Waypoints

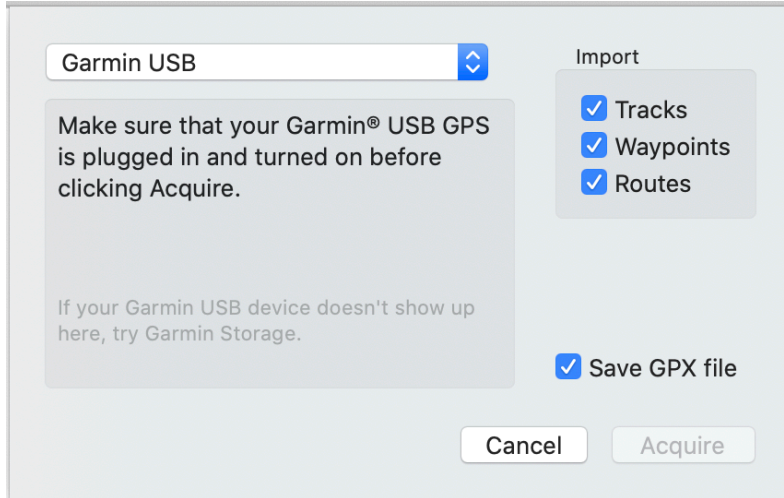

GPS Type	Special Considerations	Import Options
Lowrance	Make sure that your Lowrance GPS data card is plugged in and mounted on the Desktop before clicking Acquire.	Tracks, Waypoints, Routes
Magellan GPS	Make sure that your Magellan GPS is plugged in and turned on and that data transfer mode is selected.	Tracks, Waypoints, Routes
Magellan Serial	Select the serial port that your Magellan GPS is connected to before clicking Acquire.	Tracks, Waypoints, Routes
NMEA	Make sure that your SONY GPS is plugged in and turned on and that data transfer mode is selected.	Tracks
Timex	Make sure that your Timex Data Recorder is plugged in and turned on before clicking Acquire.	Tracks
TomTom	Make sure that your TomTom GPS is plugged in and turned on and that data transfer mode is selected.	Waypoints

GPS Import Options

3.7.1 Acquire data directly from a GPS

Acquire tracks, waypoints, and routes directly from a connected GPS device

1. Choose **File > Acquire GPS Data**.
The Acquire GPS Data window appears.

Acquire GPS Data Window

2. Select the GPS type from the menu at the top of the window.
3. Choose one or more of **Tracks**, **Waypoints**, or **Routes** to include each of those in your import
4. If you would like an external record of your GPS download, check **Save GPX File** and a GPX file will be created while the data is acquired
5. Click **Acquire**. The data is imported into Cartographica in a new layer.

⚠ It is not uncommon for tracks to come from GPS devices as single features with multiple parts. Using Cartographica's **Split Feature**, you can break these down into their constituent pieces. Similarly, if you have too many individual tracks, you can use the **Merge Features** and **Merge Selected Layers...** features to bring those together.

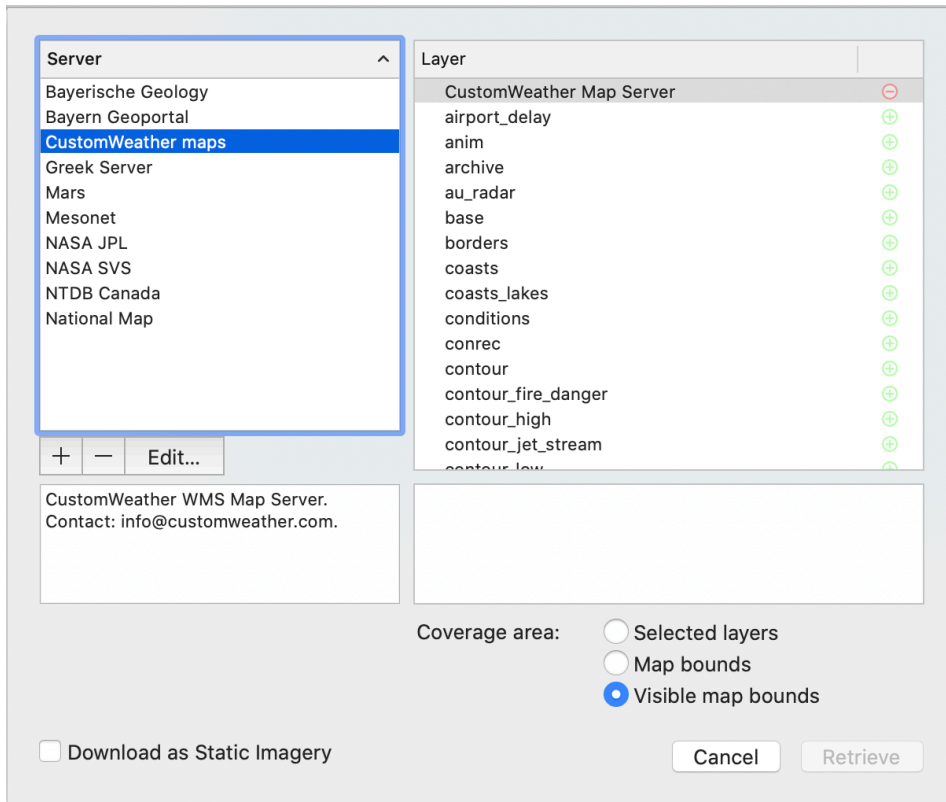

3.8 Acquiring Images from Web Map Servers (WMS)

There is an enormous amount of freely available or paid imagery available on the internet. Even after the popularity of the internet grew, exchange of imagery data online was difficult due to the wide variety of formats and protocols to access the data. This all changed with the creation of the Web Map Service (WMS) protocol as part of the work of the Open Geospatial Consortium (OGC). WMS provides a standard mechanism for browsing and specifying imagery data available from servers online and declares certain standards for the transport and representation of that data. Cartographica makes use of WMS to provide access to this ready resource of data.

3.8.1 Acquire data from a WMS Server

Acquire imagery data over the internet from a OGC-compliant WMS Server

1. Choose **File > Acquire WMS Data**.
The **Acquire WMS Data** window appears.

Acquire WMS Data Window

The server list (on the left) shows a several WMS servers from which you can retrieve data. Once you have selected a server in the list, the description box below the server list changes to give a description of the selected server as broadcast from the server. The Source list on the right will display the options available for the selected WMS Server.

2. Select the server in the left column
Cartographica will retrieve the current layer information from the server and present it on the right Layer column
3. Select one or more layers on the right
The Layer list on the right shows layers that can be added to your maps from the Server. Data marked with a red (-) cannot be added (usually because it is a category) and data marked with a green (+) can be added. When one of these sources is selected, a description appears in the box below the Source list.
In some cases, multiple layers can be added in the same request. If there is a limitation on the number of simultaneous layers that may be chosen, it will be displayed in the lower left.
4. Select the **Coverage Area** to determine how much information is downloaded from the server. The default **Visible map bounds** is generally suitable as it adds a margin around the current map's extent. **Selected layers** will limit the bounds of the imagery to the extent of the selected layers, and **Map bounds** will limit the bounds of the imagery to the extent of the current map, without any margin.
5. If want to download a copy to disk (as opposed to always fetching data from the server), check **Download as Static Imagery**
Checking this box will download a single map to your hard drive. The quality of the imagery when you zoom will be decreased, but you will be able to work on the map even when you aren't connected to the server, and your imagery will never change.
6. Click **Retrieve** to add the data to your map.

3.8.2 Add New WMS Server

Add a new server to the list of available WMS Servers

When you have the WMS Server sheet visible, you can add more servers to the source list on the left

1. Click the Add (+) button at the bottom of the left column to start adding a new server
The **Add new WMS Server** window appears.

The screenshot shows a dialog box titled 'Add New WMS Server'. It has a light gray background. At the top, there is a label 'Server Name:' followed by a text input field with a blue border. Below this is a label 'URL' followed by another text input field. At the bottom right, there are two buttons: 'Cancel' and 'Add'.

Add New WMS Server Window

2. Enter the name of the server and the URL and click **Add**. The Server will appear in the source list on the left.

3.8.3 Removing a WMS Server

Remove an existing server to the list of available WMS Servers

When you have the WMS Server sheet visible, you can remove servers from the source list on the left

1. Select the name of the server from the source list on the left
2. Click Remove (–) beneath the source list

3.8.4 Editing a WMS Server

Modifying an existing server to the list of available WMS Servers

When you have the WMS Server sheet visible, you can edit servers from the source list on the left

1. Select the name of the server from the source list on the left
2. Click **Edit...** beneath the source list
3. Change the name of the server and/or the URL and click OK

3.9 Adding Live Maps to Cartographica

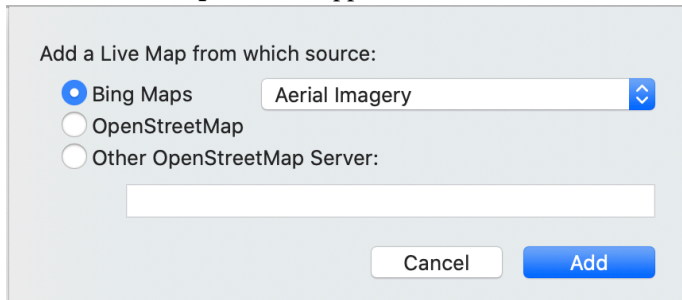

One of the biggest challenges in GIS is putting data in context. In Cartographica, we provide access to a number of Live Maps in order to make that process easier. Customers who have ongoing support and maintenance agreements with ClueTrust have access to map data from **Bing Maps**[®], and all copies of Cartographica more recent than 1.2 have access to any service compliant with the **OpenStreetMap**[™] tiling mechanism. Although the Live Maps are useful in many cases, it is important to remember that Live Maps are not vector data, and thus can't be used directly for analysis, and they are only available while the computer is connected to the internet. In addition, take care with

the coordinate reference systems, as they are generally considered quite inaccurate for precise measurements and comparisons of area and distance. However, they provide an easy visual reference for presentation and basic checking of data.

3.9.1 Adding Live Bing Maps to Cartographica

1. Choose **File > Add Live Map...**

The **Add Live Maps** window appears.

Add Live Map Window

The buttons on the left provide the selection among the different types of live maps: Bing Maps (Microsoft-provided map data), OpenStreetMap (using the main OpenStreetMap server), and Other OpenStreetMap servers (add a user-provided URL).

2. Select the imagery type from the **Bing Maps** menu, choosing Aerial Imagery, Roads, or Roads on Aerial Imagery as desired.
3. Click **Add** to add the Live Map data to your map.
A layer named **Bing Live** will appear in the Layer Stack.

3.9.2 Adding Live OpenStreetMap Maps to Cartographica

Cartographica supports servers that tile imagery in a manner described by OpenStreetMap, this includes both the OpenStreetMap site itself (usage limits may apply) and other sites complying with the same standard.

1. Choose **File > Add Live Map....**
The **Add Live Map Window** appears
2. Select the **OpenStreetMap** option.
3. Click **Add** to add the Live Map data to your map.
A layer named **OpenStreetMap Live** will appear in the Layer Stack.

3.9.3 Adding Other Live OpenStreetMap Conformant Maps to Cartographica

1. Choose **File > Add Live Map....**
The **Add Live Map Window** appears
2. Select the **Other OpenStreetMap server** option.
3. In the text box adjacent, type or paste the URL for the server.
4. Click **Add** to add the Live Map data to your map.
A layer named **OpenStreetMap Live** will appear in the Layer Stack.

3.9.4 Creating Appropriate OpenStreetMap URLs

Cartographica is flexible in how it ingests data from OpenStreetMap style tiling server, and thus can communicate with more servers than just ones that are explicitly marked as OpenStreetMap.

In order to be compatible, the map tile server must serve up tiles in the WGS 84/Pseudo-Mercator coordinate reference system (used also by Google Maps and Bing Maps).

If the server uses an OpenStreetMap url format (z/x/y in tile coordinates), then the base URL may be added directly (for example, OpenStreetMap would be "https://a.tile.openstreetmap.org"). If not, special codes may be added in the URL to delineate the positions of each of the tile coordinates. In these cases, you may put x, y, and z (or zoom) in curly brackets to represent each of the coordinates. For example, ArcGIS servers commonly are of the form:

```
http://myserver/ArcGIS/rest/services/MyMapLayerName/MapServer/tile/{zoom}/{y}/{x}
```

whereas some other servers use explicit denotation and separators, such as:

```
https://mymapserver.com/foo/x={x}&y={y}&z={zoom}&scale=2&s=Ga
```

Either of these forms are acceptable to Cartographica.

3.9.5 Printing and Publishing Considerations

As with all data that is presented on maps, you must take care to appropriately cite and honor the rights of the originating entity. In the case of OpenStreetMap, the data is explicitly open data, and as such the data itself is available under the [OpenData Commons Open Database License](#) (ODbL). The tiles themselves are released under the [Creative Commons Attribution-ShareAlike 2.0](#) license. Please refer to these when you consider publishing your data.

Bing Maps data is under copyright to Microsoft and it is important to verify your eligibility before using these in printed materials. ClueTrust has a [Knowledgebase Entry covering the issue](#). Please review this and the supporting material before publishing your maps.

3.10 Importing Vector Data with WFS

Servers that support the [Web Feature Service](#) (WFS) specification from the [Open Geospatial Consortium](#) (OGC) provide access to vector feature data over the internet. Although the protocol has been around for some time (it's been implemented in Cartographica and CartoMobile for a number of years now), it is not as popular as other online map format services, such as Web Map Service (WMS), Web Map Tile Service (WMTS). However, it has a unique feature that it actually provides geometric data instead of just visual representations. As such, the geometric fidelity and associated information can be substantial. In addition, there is a writable version of the service (WFS-T, Web Feature Service-

Transactional) which can be used to write data back to the server. Although Cartographica does not support WFS-T as of this writing, CartoMobile does support it as a mechanism for implementing remote data collection.

Cartographica considers WFS to be a data source, but locally caches information retrieved from the server so that it can be used offline.

3.10.1 Acquire data from a WFS Server

Acquire feature data over the internet from a OGC-compliant WFS Server

1. Choose **File > Add Web Feature Layer...**

The **Add Web Feature Layer** sheet appears.

2. Type or paste the URL for the WFS server into **Server URL**
3. Type or paste the name of the chosen layer into **Layer**
4. Click **Add**

Cartographica will add a layer to the *Layer Stack* with the name of the layer and will retrieve the information from the WFS server. If the server is unavailable or requires a password, you will be prompted for any supplemental information.

3.10.2 Filtering data from a WFS Server

There are times when a WFS layer contains a combination of relevant and irrelevant data. In those cases, the **Filter** box in **Add Web Feature Layer** can be used to limit what is downloaded from the server. The form of the filter is an expression that is evaluated by the WFS server and can be pretty esoteric. It is suggested that if you want to filter the information, you coordinate with your WFS server administrator or consult the documentation for the provided layers in order to determine the format and function of the filters. Some examples follow.

- ```
<ogc:PropertyIsGreaterThan>
 <ogc:PropertyName>DATE_</ogc:PropertyName>
 <ogc:Literal>'2012-09-15'</ogc:Literal>
</ogc:PropertyIsGreaterThan>
```

This filter looks for features that have property that is named DATE\_ which is greater than 2012-09-15. The formatting needs to be precise and Cartographica will validate it with the server, so that you can make changes and re-submit if necessary.

- ```

<ogc:And>
  <ogc:PropertyIsGreaterThan>
    <ogc:PropertyName>DATE_</ogc:PropertyName>
    <ogc:Literal>'2012-09-15'</ogc:Literal>
  </ogc:PropertyIsGreaterThan>
  <ogc:PropertyIsEqualTo>
    <ogc:PropertyName>SOURCE</ogc:PropertyName>
    <ogc:Literal>BIC</ogc:Literal>
  </ogc:PropertyIsEqualTo>
</ogc:And>

```

This more complex filter builds upon the previous filter and also requires that the SOURCE property be equal to the BIC. Note the use of the outer And command to dictate that feature match both conditions. You could also use an Or here to dictate that matching either condition be matched. The specific operators available may vary by server, but they generally take the same form and are always represented by XML.

3.10.3 Editing Existing WFS Layers

To edit an existing filter, choose **Layer > Web Feature Layer Attributes...** and you will be presented with the **Add Web Feature Layer** sheet again. Once you click **Save**, the filter is re-run and any new items are added to the local copy of the layer. It's important to remember that existing features are not deleted, so you will have to manually remove them if you want them taken out of the layer.

4 Exploring Data

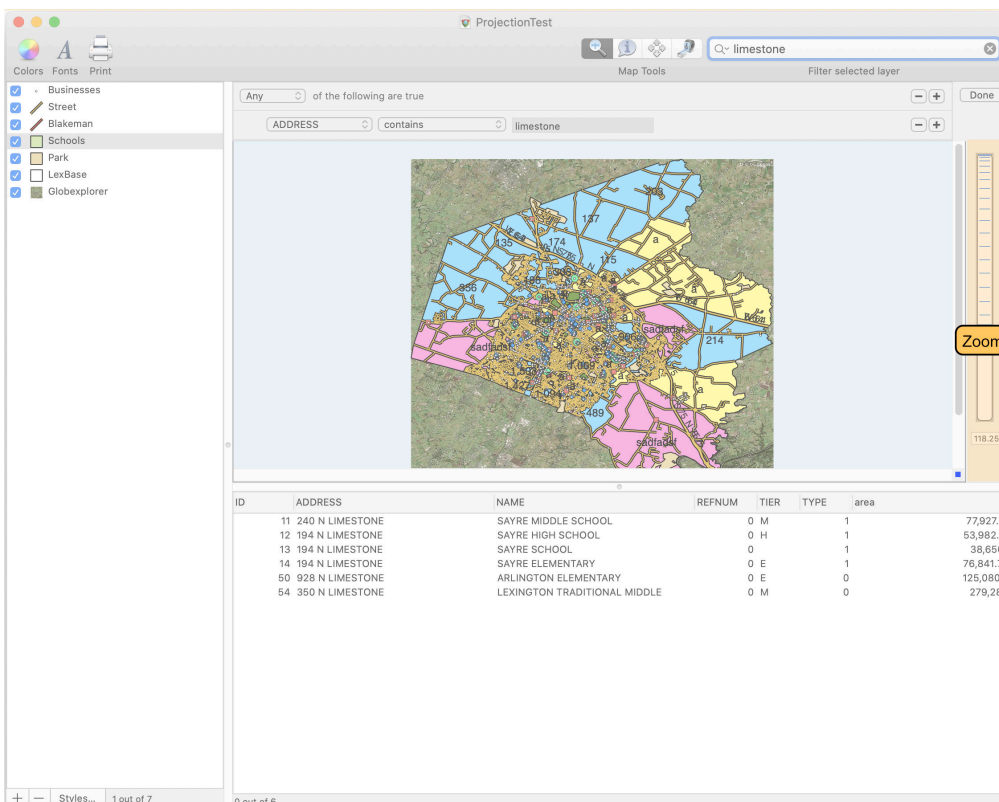

Learn the basics of exploring data with cartographica

Cartographica is first and foremost a tool for exploration of data. This chapter describes many of the tools available for visualizing the data that you have. In concert with the analysis and presentation features, these tools provide a robust starting point for understanding the information within your data.

4.1 Zooming In and Out of Maps

There are several ways to zoom in and out of a map:

- Use the scroll wheel on the mouse while holding down the Option key on the keyboard
- Use the *Zoom Dial* on the right side of the Map Windows
- Use the Zoom To menu items in **View** to jump to particular zoom levels
- Use the zoom tool to zoom to points or areas using the mouse pointer
- Use the **Previous Extent** and **Next Extent** items in **View** move to the previous or next zoom locations

Click and hold the zoom dial and move it up to zoom in and down to zoom out.

You can also zoom by clicking your mouse when you are using the Zoom tool. The Zoom tool also has a toolbar icon looks like this:

When the Zoom tool is selected, the cursor becomes a small little magnifying glass. Click anywhere in the map to zoom in and center the map on that point. To zoom back out, click while holding the Option key on your keyboard.

You can also zoom by selecting an area with the mouse (like drawing a box around it) when you have the Zoom Tool toolbar icon selected. You will zoom in to the borders of the box you just drew.

To go to the last Zoom use the **Previous Extent/ Next Extent** menu options available in the **View** menu. Essentially, these options are undo/redo for zooming, but work independently of the action undo/redo stack.

4.2 Selecting Data and Using the Identify Tool

The Identify tool allows you to draw around an area of features on the map or click one feature directly and make the data about that feature appear in the data window. To activate the Identify tool, choose

Map > Identify Tool or click on the Identify Tool icon () in the **Map Tools** toolbar.

Use the Identify tool to identify any feature in the currently selected layer. When you select the feature by either clicking on it, or surrounding it with a rectangle that you can draw (also good for selecting multiple features) the chosen items are highlighted in the data window.

For additional information display, choose **Window > Selection Info** to display the **Selection Info** window, which displays a scrolling list of information about each selected item. This is particularly useful if you have a lot of items selected which aren't next to each other in the data view, or if you have closed the data view to maximize map area.

Layer	ID	Attribute	Value
Schools	20	ADDRESS	1600 MAN O WAR BLVD
Schools	21	NAME	PAUL LAURENCE DUNBAR HIGH
Schools	22	REFNUM	0
Schools	23	TIER	H
Schools	24	TYPE	0
Schools	25	area	1,916,670.24311
Schools	26	len	6,570.47408348
Schools	27		

Selection Window

4.2.1 Selecting data using an existing feature

Cartographica contains a number of tools that allow you to select data in a layer (and in some cases on other layers) based on a selected feature. These tools are found in the **Edit** menu.

Menu Item	Description
Select All	Selects all items in the current layer
Select Similar	Selects all items that have the same style (on layers with a single style, this is the same as Select All)
Select With Feature...	Selects items using a Spatial Join tool (intersection/overlap/etc) as described in Spatial Join . This will be Select With Features... if multiple features are currently selected.
Select With Layer's Features	Selects items using a Spatial Join tool (intersection/overlap/etc) as described in Spatial Join (only enabled when a vector layer is selected and no features are selected).
Invert Selection	Select only the features that are not currently selected.

4.3 Using the Pan Tool to Move a Map

You can use the Pan tool to grab and move the map to change the view. To use the Pan tool, choose

Map > Pan Tool or click the Pan tool icon () in the **Map Tools** toolbar.

Once you have selected the Pan tool toolbar icon, the cursor becomes a small hand with which you can move the map within the map window. Click the mouse at any point and then drag to move the map.

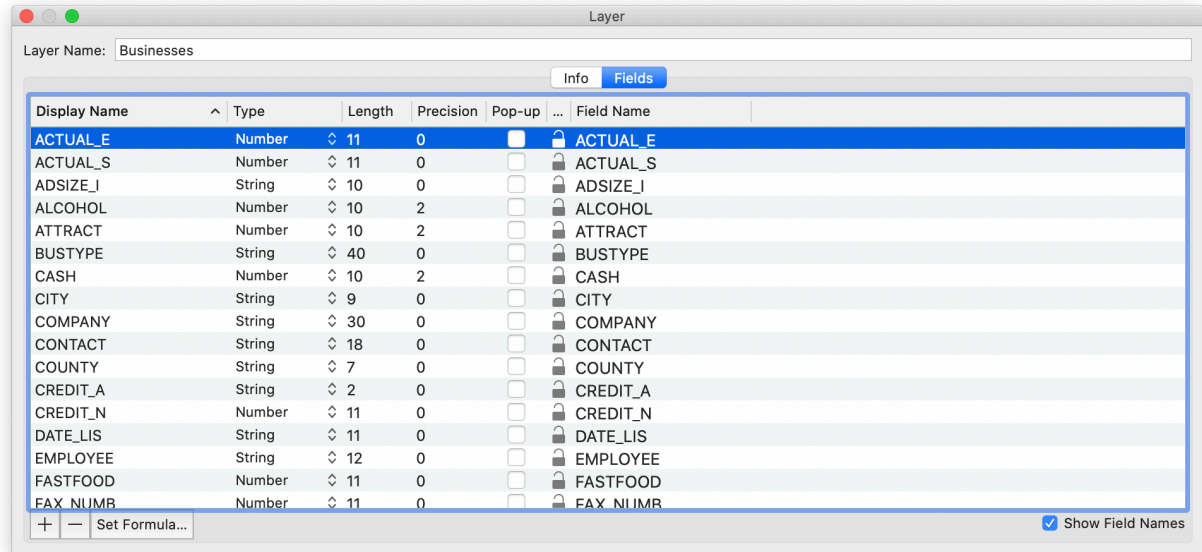

4.4 Data Tooltips

Data Tooltips show you summary information about selected features. By holding down the Option key while moving over any item in the selected layer, a small window will appear with information about the item you have moved over. The information that appears is defined in the Layer Info window.

Further, if you prefer to have Data Tool Tips available at all times without having to hold the option key, you can toggle them by choosing **Map > Show Data Tooltips**

4.4.1 Specifying Data Tooltip information

1. Choose **Windows > Layer Info** to bring up the **Layer Info** window.

1. Select the **Fields** tab to show the information about the columns
2. Check the **Pop-up** box on the line corresponding to the desired field.

⚠ The summary data is also used as the description information that is exported when using the KML exporter.

4.5 Measuring Distance and Area

You can measure distances and areas using the Measure tool. To activate the Measure Tool, choose **Map > Measure Tool** or click the Measure Tool () in the **Map Tools** tool bar.

Once you have selected the Measure Tool, you can use the mouse to measure distances and areas. Any measurements you make appear in the **Measurements** window, which appears when you begin your first measurement.

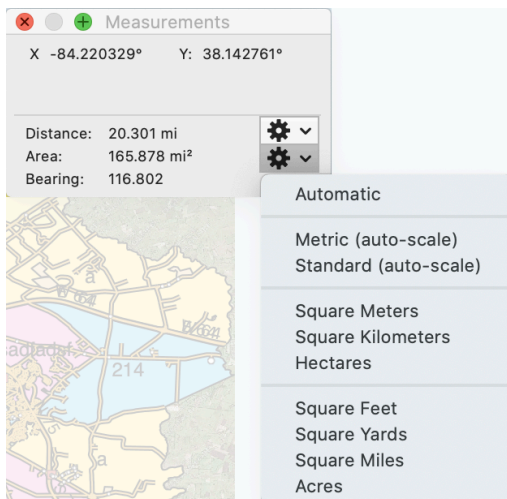

In the **Measurements** window:

- **X** and **Y** show the location (in map coordinates) of the mouse click (or just of the location of the cursor if you are not holding down the button).
- **X2** and **Y2** show the location (in map coordinates) of the cursor if you are holding down the mouse button.
- **ΔX** and **ΔY** show the coordinate differences between **X** and **X2**, and **Y** and **Y2** respectively (also in coordinate units).
- **Distance** is the distance of a straight line from **X,Y** to **X2,Y2** in linear coordinates.
- **Area** is the area of a rectangle bounded by **X,Y** and **X2,Y2** in linear coordinates. Essentially the line you create is making the diagonal for a rectangle that is bound by those points.

⚠ ΔX and ΔY are in linear or angular coordinates depending upon the coordinate system of the map. However, distance and area are always in linear coordinates, using the great-circle method when the coordinate system of the map is natively angular.

- **Bearing** is the bearing (relative to the X axis of the data) from **X,Y** to **X2,Y2**.
To change the units for the measurements, select one of the gear drop down menus in the measurement window and choose the units. Units can be controlled and the scale itself may be restricted to a fixed size (in units). When using fixed unit size, the units will be adjusted to the next larger unit if the value could not be displayed in the available space.

To use the tool to measure distance:

- To measure a line or distance between two points, select the Measure Tool toolbar icon. Click on the first point from where you want to measure, hold the mouse button and drag the cursor to the second point. The distance between those points will be displayed in the Measurement window.
- To measure area, select the Measure Tool toolbar icon, place the cursor over one boundary corner of the area you want to know and then click and hold the mouse button down until you drag the cursor to the other boundary corner of the rectangle you want to measure. The area of the rectangle appears in the Measurement window.

⚠ Default Units

Since 1.5.4, the Cartographica Preferences window contains preferences that control the units that are used as the default units for new Maps (for both area and linear measurements). These preferences are used for *new* documents, and the selections in the **Measurements** window are retained with the document when it is saved.

4.6 Using the Data View

Most GIS data has geospatial information in the form of features (points, lines, and polygons) and non-geospatial data, which may consist of just about anything you can imagine: place names, number of crimes in an area, type of pavement on road. This data is sometimes displayed on the map as labels, represented by colors, or visualized in other ways.

The data view is located at the bottom of the main Cartographica window. This is a standard Mac OS X table, and works the same as other tables on the platform.

ID	AREA	COD	NAME	POP1991	POP91_SQMI
1	585,860.072	CA10	Quebec	6,895,963	13.164
2	1,320,278.813	CA06	Northwest Territories	57,649	0.045
3	21,199.186	CA07	Nova Scotia	899,942	44.11
4	251,738.905	CA11	Saskatchewan	988,928	4.488
5	256,873.619	CA01	Alberta	2,545,553	10.231
6	152,523.521	CA05	Newfoundland and Labrador	568,474	3.961
7	364,449.495	CA02	British Columbia	3,282,051	9.143
8	27,996.778	CA04	New Brunswick	723,900	26.008
9	2,207.134	CA09	Prince Edward Island	129,765	59.389
10	186,112.055	CA12	Yukon Territory	27,797	0.15
11	251,261.199	CA03	Manitoba	1,091,942	5.157
12	380,275.566	CA08	Ontario	10,084,885	29.309

1 out of 12

The layer that is shown in the data view is the layer that is currently selected in the layer stack. If you are looking at the screen and wondering why the data you're looking for is not what you expect, check the layer stack and make sure the layer you are interested in is selected. If you have more than one layer selected in the layer stack, no data will be shown in the data view.

Further, the selection in the data view is synchronized with the selection in the map view, which means that if you select a feature in the map view, the data view will scroll such that the information about that

feature is visible. Similarly, if you click on a row (or rows) in the data view, the corresponding map view features will be selected.

4.6.1 Sorting the Data View

1. Click on the heading for the column on which you would sort the view
The table will sort to your specifications and an arrow will be displayed at the right side of the header to indicate the sort order.
2. To sort in the opposite order on the same column, just click again in the column heading.

Re-ordering columns in the Data View

1. Click on the column heading and drag it to the new location
The column will move from its old location to the new location

Editing data in the Data View

Editing most of this data is very straightforward as it is done directly in the data table below the main Map in the Map Window. Once you have a layer selected, click on the individual cell of data and start typing.

1. Select a single layer in the layer stack
Cartographica will display the data for this layer in the data view
2. Select a feature by doing one of the following
 - Click on a feature in the map
 - Click on a row in the table
 The feature will be selected in both the map and the Data View.
3. Click in the column to change
The blue focus box will show up around the table cell indicating that you may now enter your data

 Columns which have been locked or which contain Column Formulas cannot be edited and will not enable when clicked.

4. Press the enter key to finish editing

Locating the selected data on the map

There are times, especially when working with the Data View that you can't easily locate the data you have selected on the map. Cartographica has a couple of different ways to view these.

1. Select the item that you want to locate on the map using the Data View
2. Tap and hold the space bar
The selected feature(s) will appear zoomed out to the full size of the Map View. When the space bar is released, the feature will recede slowly into its position on the map. This is most useful when you just want to locate, but not move the focus of the map
3. Choose **View > Zoom to Selected Feature**
The Map View will be zoomed to an area encompassing the selected feature(s). This is most useful when you are interested in seeing the detail of a feature.
4. Click on the heading for the column on which you would sort the view
The table will sort to your specifications and an arrow will be displayed at the right side of the header to indicate the sort order.

5. To sort in the opposite order on the same column, just click again in the column heading.

4.6.2 Re-ordering columns in the Data View

1. Click on the column heading and drag it to the new location
The column will move from its old location to the new location

4.7 Adding, Removing, and Renaming Columns

Columns may be added to and removed from any layer. There are some restrictions on exactly how this is done.

Layer Type	Restrictions
All By Reference Layers	Columns added to By Reference layers will require either internal saving or updating the original file to keep their data. This only happens when you save the Map Set, so if you are doing this temporarily there is no harm. The only exception to this are Formula Columns, which are only stored in the Map Set and can continue to use the By Reference data.
WFS Layers	Columns added to WFS Layers will not create new columns on the server. Any data that is added to these layers will be lost when the Map Set is saved and re-opened. As with By Reference layers, Formula Columns will have their data recomputed on load and thus will not be lost when saving a Map Set.
Live Maps	There are no features and thus no columns for Live Maps.

Column Change Restrictions

Columns of any data type may be added in Cartographica. By default, the Add Column command from the Layer menu will add a String column, which can represent textual or numeric data.

4.7.1 Adding Columns to a Layer

1. Select the layer in the Layer Stack
2. Choose **Windows > Show Layer Info** to bring up the Layer Info window
3. Click the **Fields** tab to show the list of columns
4. Add a column by doing one of the following:
 - Click +
 - Choose **Layer > Add Column**

A new column will be added to the column list and brought into view

5. Optionally change the type of the column by selecting from the corresponding **Type** cell
6. Optionally change the size of the column by clicking in the corresponding **Length** cell

4.7.2 Removing Columns from a Layer

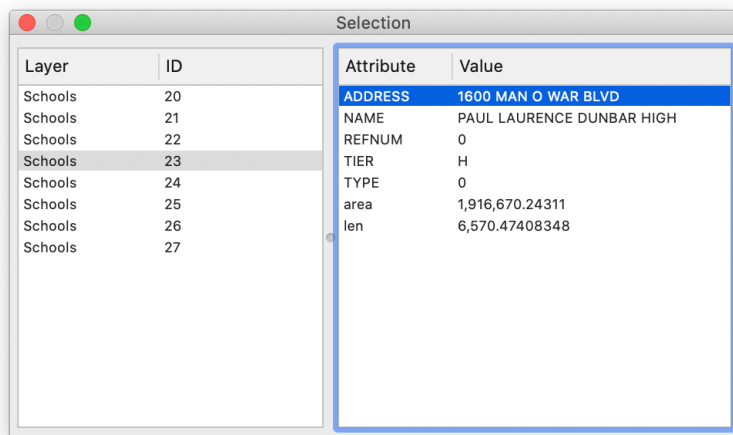

1. Select the layer in the Layer Stack
2. Choose **Windows > Show Layer Info** to bring up the Layer Info window
3. Click the **Fields** tab to show the list of columns
4. Select the column to remove
5. Remove the column by doing one of the following:
 - Click –
 - Choose **Layer > Remove Column**
6. The selected column will be removed from the column list

4.7.3 Renaming Columns in a Layer

1. Select the layer in the Layer Stack
2. Choose **Windows > Show Layer Info** to bring up the Layer Info window
3. Click the **Fields** tab to show the list of columns
4. Select the column to rename
5. Click in the corresponding **Name** cell and type the new name
The selected column will be renamed

4.8 Using the Selection Window

The Selection Window shows information about the features you select in the data window. To access the Selection window, choose **Windows > Show Selection Info**.

The **Selection** window is best used for looking at specific data when you have multiple items selected in the map or data view.

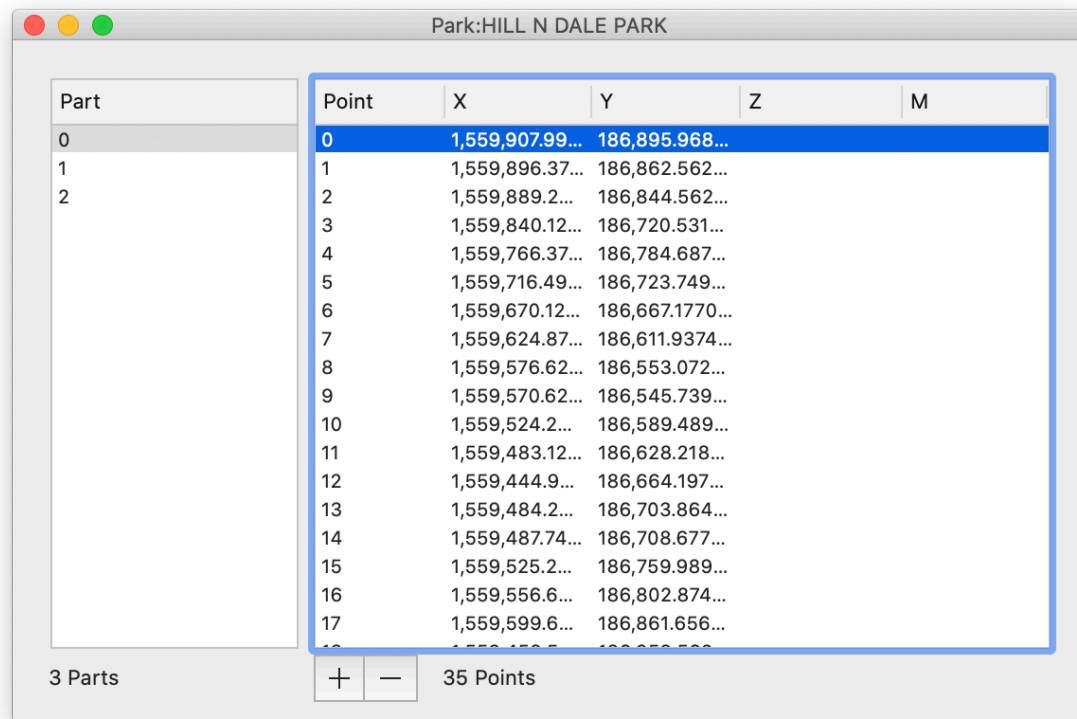

The left-hand side controls what information is available in the right-hand side. By double-clicking on the left hand side, the Data View and the map view window will change to show only those items selected in the column on the left-hand side.

4.9 Using the Point Data Window

The **Point Data** window is used for looking at the detailed geometric data of a feature. To open the Point Data window, choose **Window > Show Point Data**.

All data in the **Point Data** window is expressed in the original coordinates. Modifying geometric points will cause those points to be reprojected onto the current map's coordinate system.

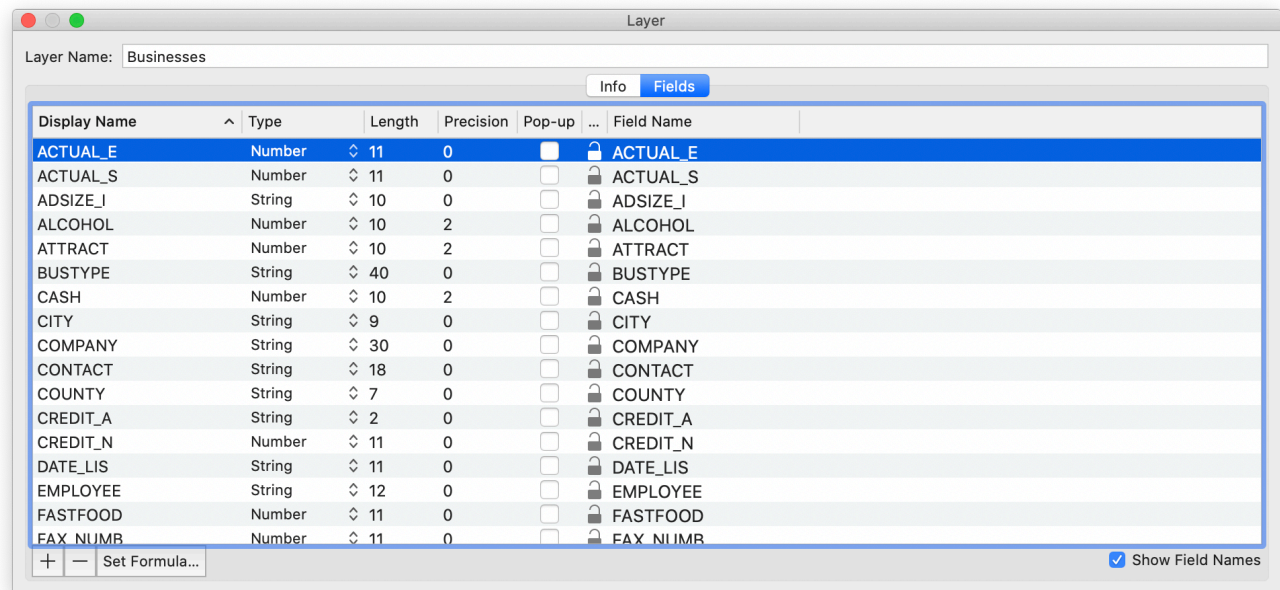

⚠ Generally, it is easier to edit if Maps and Layers are (at least temporarily) set to the same value.

Use the left side of the window (**Part**) to select the part within the feature (many features have only one part, but others may have many). The right side of the window (**Point**) shows the list of points in the selected Part. In the case of a Line, a part describes disjoint line segments. In the case of a Polygon, the parts describe islands or holes in the Polygon.

4.10 Additional Layer Info

From the Layer Info Window click the **Info** Tab. The Info tab appears.

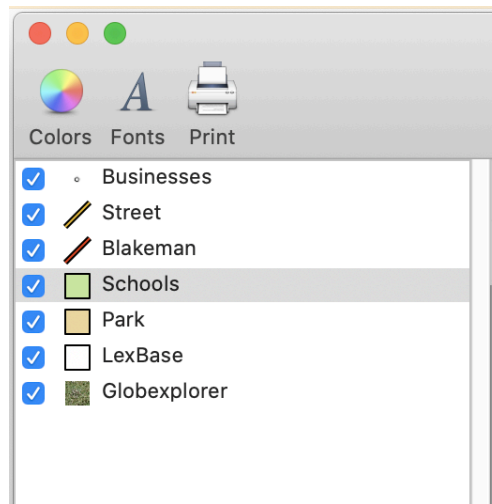

The Info tab displays some additional information about the Layer.

Representing	This pop-up menu describes the information that this layer represents. This serves only as a guide for the software and for users.
Feature Name	This pop-up determines which column in the data for this layer is used as the feature name during display. This affects certain output formats (such as KML) which have use for a name field and is displayed in Data Tool Tips.
Geometry	Describes the type of features represented in this layer. Possible values are: Point, Polyline, Polygon, Image.
Objects	Provides a count of the number of features in this layer.
Points	Provides a count of the number of points in all features in this layer. This is a rudimentary measurement of complexity.
Bounding Box	Shows the upper left and lower right coordinates of the bounding box in map coordinates.
Base Box	Shows the upper left and lower right coordinates of the bounding box in layer coordinates.

5 Working With Layers

5.1 Using the Layer Stack

The Layer Stack appears on the left side of the Cartographica Window. This view shows all of the different layers of data that appear in the map.

Layer Stack

The Layer Stack defines what appears in the Map View and Data View.

You can drag items to re-order them in the layer stack. Top is "on top" if you were to think of it as a layer cake or a set of papers layered on top of each other. Often, if you are using a raster layer, you'll drag that to the bottom so that all the vector content sits "above" it.

You can also drop a layer on another layer to copy styles from the dropped layer to the dropped-on layer. Although it might seem strange, you can also drop a layer on another layer of a different type. This allows for an easy way to copy the color schemes.

5.1.1 Showing and Hiding layers

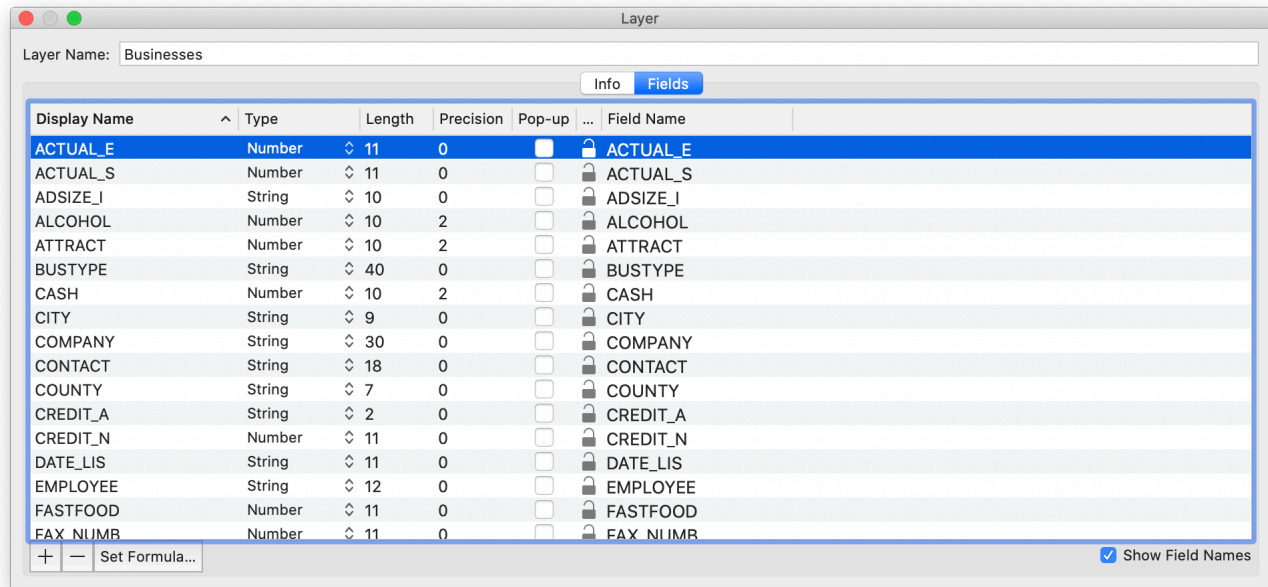

You can choose which layers are shown on the map by doing one of the following:

- Toggling the check box next to the layer name in the layer stack
- Choose **Layer > Hide Layer** or **Layer > Show Layer**

When you do hide a layer the features contained in this layer are no longer seen on the Map.

5.2 Using the Layer Info Window

The **Layer Info** window shows the data features of the layer that is selected. It is used to add/remove columns, change data types, and modify column names. To access the Layer Info window, choose **Window > Show layer Info**. The **Layer Info** window appears showing the **Info** tab.

Layer Info Window

The **Layer Info** is a live window, so you can make changes to the layer by editing the values in it. Here is a description of each of the columns in the **Layer Info** and their purpose.

Column Name	Purpose
Display Name	The name used by the Data View and the Legend, and has very few practical limitations, other than needing to be unique.
Type	Type of the data in this column. This determines how the data in the column is to be interpreted by Cartographica. Possible types are: String, Float, Number, Boolean, and Date.
Length	The storage length for this column. This will determine the maximum length of a string, the maximum number of digits of a Number column, etc. Float, Date, and Boolean should be left at the system suggested values.

Column Name	Purpose
Precision	For the Number column (fixed digits), this is the number of digits of the Length field that are dedicated to numbers after the decimal point.
Pop-up	If this is checked, this column is used in the Pop-up preview (for example, if you hover over a feature)
Lock	Determines if this field is locked. This is mostly used with the calculated formulas (see Column Formulas) columns, as it will prevent these from being re-calculated.
Field Name	This is the actual data storage name internally. Generally, you're better off not to change these unless you know you're going to be re-exporting SHP-file data and you need to match column names with other software.

For example, to change the **Display Name** (the name that shows up in the **Data View**) for ACTUAL_E, click on the word and then type a new name. Similarly, the length, precision, and type of data can be manipulated by making changes to those columns.

⚠ If you change a column's type, Cartographica will attempt to coerce the data in that column to the new type, but that may not always be possible. Take particular care when converting textual data to numbers, as you are likely to end up with many 0's if the data cannot be reinterpreted.

5.3 Filtering on Layers Using the Filter Box

You can use the **Filter this layer** (the Filter Box) from the main window to filter map data within a layer and to create new data layers with the results. The Filter Box appears in the top right of the main Cartographica window.

Enter the data you want to filter into the search box. As you type, the results are narrowed and are displayed (filtered) in the data window. This filter is extremely fast, even for large datasets and is the preferred method for finding an item in the data window. Use the Filter Box with **Layer > Create Layer from Selection** to split off data that is interesting for further analysis. The filter operates on the layer

currently selected in layer stack. The filter works by filtering the data in the selected layer as shown in both the data and map views. You can also use extensions such as commas to further filter results.

And/or and multiple-field data filtering is now possible and easy with this new system. The existing filter box works as a short-cut, translating queries into the new system, which can then be edited.

As you type into the filter box, you will see a drop-down area at the top of the Map View that contains a much more flexible filtering system.

You can select which filter or all filters to use by selecting either **Any**, **All**, or **None** of the following are true.

The first selection drop down menu (shown as **Address** in the screen above) is a menu to select which column in the data window you want to search.

Then you can select if you want the filter to be **is the less than**, **is greater than**, **is** or **contains** the filter phrase.

The text box contains the text you enter that you want to filter on.

You can click the + or - button to add or remove additional filters.

Click the **Done** button to dismiss the additional Filter boxes and restore the maps and data views to all features in the selected layers.

You can also filter using variables from the same or multiple fields. This is useful for creating new layers.

5.4 Adding and Removing Layers

Although most layers are added to Cartographica map sets by importing them from existing files or network services, it is quite reasonable to create a layer yourself. Most frequently the goal of adding a layer is manually create some new features (such as drawing an area over an existing map).

5.4.1 Adding New Layers

Adding new layers to an existing map

1. Do one of the following:
 - Choose **Layer > New Layer**
 - Click on the Add(+) button under the Layer Stack

The new layer is added with no data and the a default name

2. Click on the name in the Layer stack to select the text and then replace with your new name

5.4.2 Removing Layers

Removing existing layers from an existing map

1. Select the layer you wish to remove in the Layer Stack
2. Do one of the following:
 - Click on the Remove(-) button under the Layer Stack
 - Choose **Layer > Delete Layer**
3. The selected layer is removed

5.5 Adding a New Layer Based on a Data Selection

If you want to create a new layer from a selection of data in your map, select the data you want to add to a new layer in the Data window. Now, choose **Layer > Create Layer from Selection**.

You can also select a data set using the filter bar to create a filtered list of data to create a new layer from.

This creates a new layer that will appear in the Layer stack from the selected features in the current layer, copying the styles and all data attributes.

5.6 Merging Layers

Cartographica can merge layers with similar data into a single layer, creating a new layer with the contents of all the selected layers, and removing the original layers.

This is commonly used to put like data together in a single layer for easy manipulation.

Consolidating layers will remove all of the selected layers from the map and replace them with a single layer that has all of the features of the selected layers.

- Layers must contain the same kinds of features (points, lines, or polygons).
- Layers with different dimensionality (2D, 3D, or 4D) will be upgraded to the highest dimensionality of the set.
- Optionally, you can choose to consolidate data fields for layers containing columns of the same name by clicking the Consolidate data fields with the same name checkbox. Columns with different names will be appended and the data for the other features will be left blank.

5.6.1 Consolidate Layers

1. In the Layer Stack, select the multiple layers you want to merge, by command-clicking the mouse on each layer.
2. Choose **Layer > Merge Selected Layers**
The Merge Selected Layers dialog appears.

Consolidating layers will remove all of the selected layers from the map and replace them with a single layer that has all of the features of the selected layers.

- Layers must contain the same kinds of features (points, lines, or areas).
- Layers with different dimensionality (2D, 3D, or 4D) will be upgraded to the highest dimensionality of the set.
- Layers with columns with the same name will be consolidated, columns with different names will be appended and the data for the other elements will be left blank.

Inherit styles from: Street

☒ Consolidate data fields with the same name

☐ Add original layer name in FromLayer field

Layers to be consolidated:

Street

Blakeman

Cancel Consolidate

Merge Selected Layers

3. If you would like to add a column to each entry in the new layer stating which layer the entry originated from, check **Add original layer name in From Layer field**.
4. Choose which Layer the styles come from using **Inherit styles from** drop down.
5. Now click **Consolidate**

5.7 Masking Data for Analysis Layers

When using an analysis layer (for now only created by the Kernel Density Map), often the analysis layer has a significant amount of data falling "outside" of the area of interest. To help remedy this, Cartographica can constrain the bounds of the analysis layer to the area of a polygon layer.

Below are examples of an analysis layer, the mask to be applied, and the resultant masked analysis layer. In this case, we use a Kernel Density Map and have a satellite map in the background as illustration.

5.7.1 Masking an analysis layer

Add a polygon mask to an analysis layer

In order to mask an analysis layer, you need to have a polygon layer that specifies the area you want included in the analysis. You can either use an existing polygon layer, or create one manually or using tools such as Cartographica's **Tools > Make Convex Hull**

1. Select the analysis layer in the layer stack by clicking on it
2. Select the polygon layer in the layer stack by holding the option key while clicking on it
3. Choose **Layer > Set Mask Layer**

After a few seconds, the analysis layer will be masked by the polygon layer you selected.

⚠ The mask layer will work even if the mask layer is hidden, so you can add a layer to act as the mask, assign it to the analysis layer, and then hide the mask layer without losing the mask effect, but without having whatever data is in that layer displayed.

5.7.2 Removing an analysis layer mask

Remove a polygon mask from an analysis layer

1. Select the analysis layer in the layer stack by clicking on it
2. Choose **Layer > Clear Mask Layer**

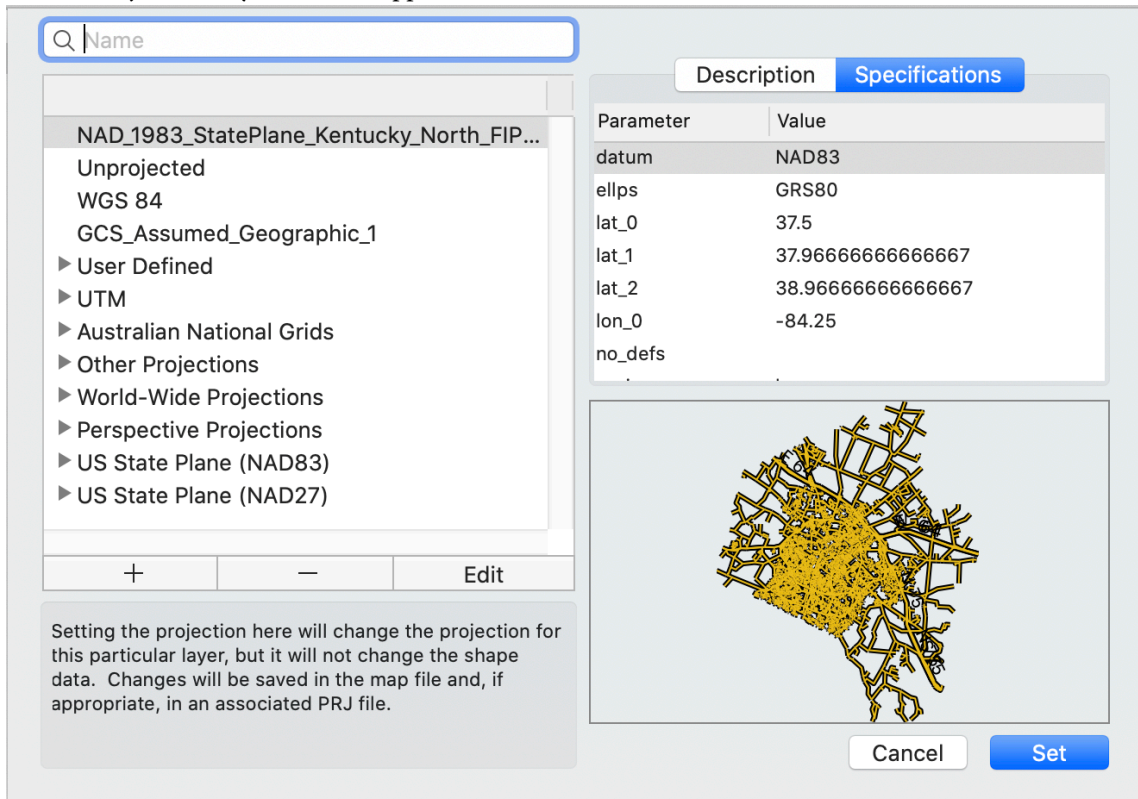

5.8 Setting Layer Projection

In the event that a layer of data is imported without any projection information, **Layer > Set Layer Projection** can change the projection without modifying the data.

It is common for data that comes in csv form to be delivered in a State Plane Coordinate System instead of Latitude/Longitude (which will be automatically selected in most cases). In the case that the projection information is not there, use the following process to set the layer projection.

5.8.1 Change Interpretation of Layer Coordinate Data

1. **Layer > Set Layer Projection** to set the layer's projection information.
The **Set Projection Layer** Window appears.

Set Layer Projection Window

Setting the projection here will change the projection for this particular layer, but it will not change the shape data. Changes will be saved in the map file and possibly in an associated PRJ file.

2. From the left side of the dialog, choose the map projection that best suits your needs.
The **Description** box on the right will change depending which projection is selected. You can also click the **Specifications** tab to see additional details about the selected projection.
Below this informational area there is a small preview area that gives a general orientation for the features of your map once the selected projection has been confirmed.
Here you should use the filter box to search for a projection.
The feature projection shape is previewed on the right side of the window so you can get an idea of what the selected projection will look like.
3. Once you have the selected the projection that best suits your needs and most accurately represents the data you are attempting to display, click Set.

5.8.2 Reprojecting Layers

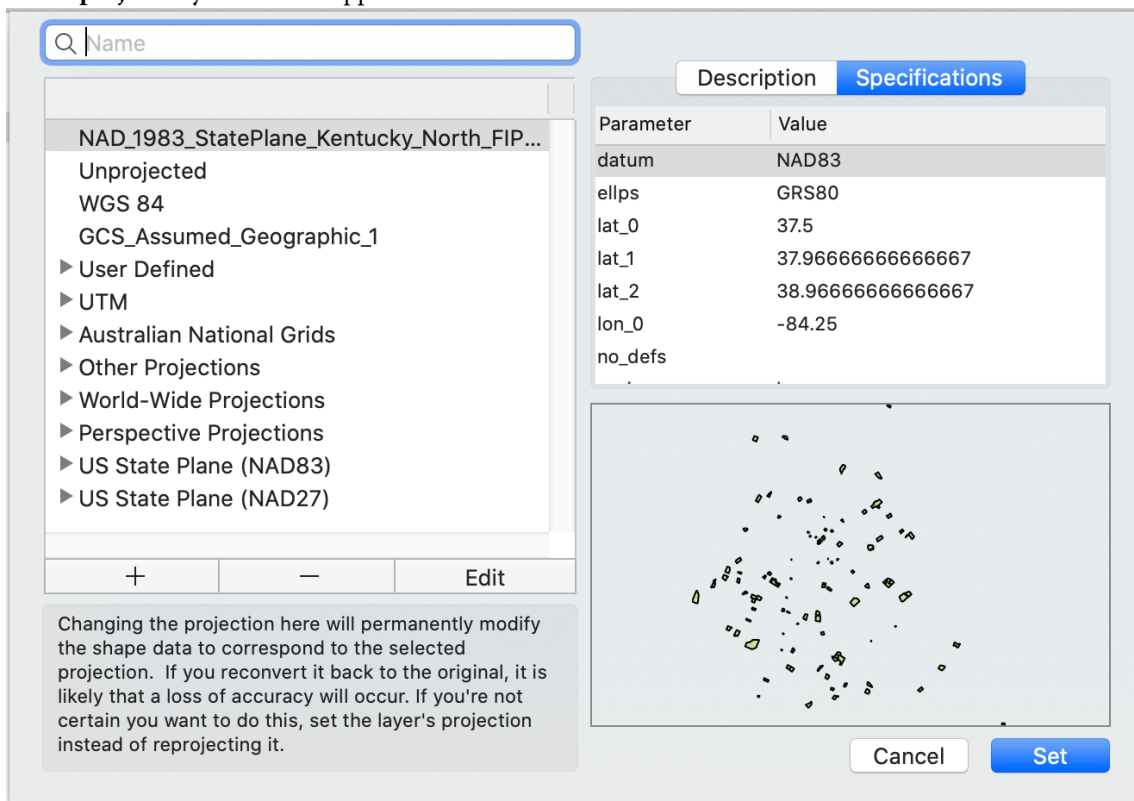

Cartographica allows users to change the geographic projection of data to several predefined datums. The limited applications include preparing data for export in another CRS.

For example, if you need a shape file in WGS84, but you have data in State Plane, you can use **Layer > Reproject Layer** to change the data from the State Plane to WGS84 and then use the Export Layer command to export it.

⚠ This is seldom the case, so most often, you can use **Map > Project Map** to set the map projection or **Layer > Set Layer Projection** to change how the features in a particular Layer are interpreted.

Permanently Change Layer Coordinate Data

1. Choose **Layer > Reproject Layer**.
The **Reproject Layer** Window appears.

Reproject Layer Window

Changing the projection here will permanently modify the shape data to correspond to the selected projection. If you reconvert it back to the original, it is likely that a loss of accuracy will occur. If you're not certain you want to do this, set the projection.

- From the left side of the dialog, choose the map projection that best suits your needs.
The **Description** box on the right will change depending which projection is selected. You can also click the **Specifications** tab to see additional details about the selected projection.
Below this informational area there is a small preview area that gives a general orientation for the features of your map once the selected projection has been confirmed.
- Once you have selected the projection that best suits your needs and most accurately represents the data you are attempting to display, click **Set**.

5.9 Referenced Data

Cartographica tries to be intelligent about referencing external data in order to maximize efficiency and convenience. In many cases, Cartographica can make an external reference to a file instead of making it part of the Mapset. This data is referred to as being Externally Referenced.

When a layer is Externally Referenced, it has a by reference icon () in the layer stack on the right side. Also, when that layer is selected, the **Layer > Include Layer Data in Mapset** item is unchecked.

Often, storing boilerplate data and large imagery in external files is desired to save space and to make updating that data easy. Imagine having a set of 10 maps that all need road information, but your road information changes on a monthly basis. If your road polygons are kept in an external file, you need only update the external file, load your mapset and the information is up-to-date.

The main reason to use this is if you need to "Freeze" the data for a particular layer so that you don't accidentally change it.

5.9.1 Bringing External data into the Mapset

- Select the desired layer from the Layer Stack
- Choose **Layer > Include Layer Data in Mapset** to bring the data into the Mapset. The next time you save, a copy of the data will be made inside of this Mapset.
Once a data set is brought into the Mapset, the only way to make it external again is to delete the layer with the internal copy and re-import the data.

Occasionally, you may need to create a copy of a Cartographica Mapset for distribution to other parties or to archive the complete state of a map and all its constituent parts. In this case, often it is necessary to put all of the data into the Mapset file before sending it because the recipient may not have the original files. Since permanently changing this might not be desired, you can save a copy of your Mapset file that has had all of its layer data brought internal, or "flattened".

5.9.2 Flattening a Mapset

- Choose **File > Save As...** to begin the saving process
- Check **Flatten Map When Saving** to flatten the file
- Now choose a file name and click **Save**

6 Working With Styles

Styles determine how a map looks when viewed, printed, embedded in a map layout, or exported to any style-conscious format (such as Adobe Illustrator or KML).

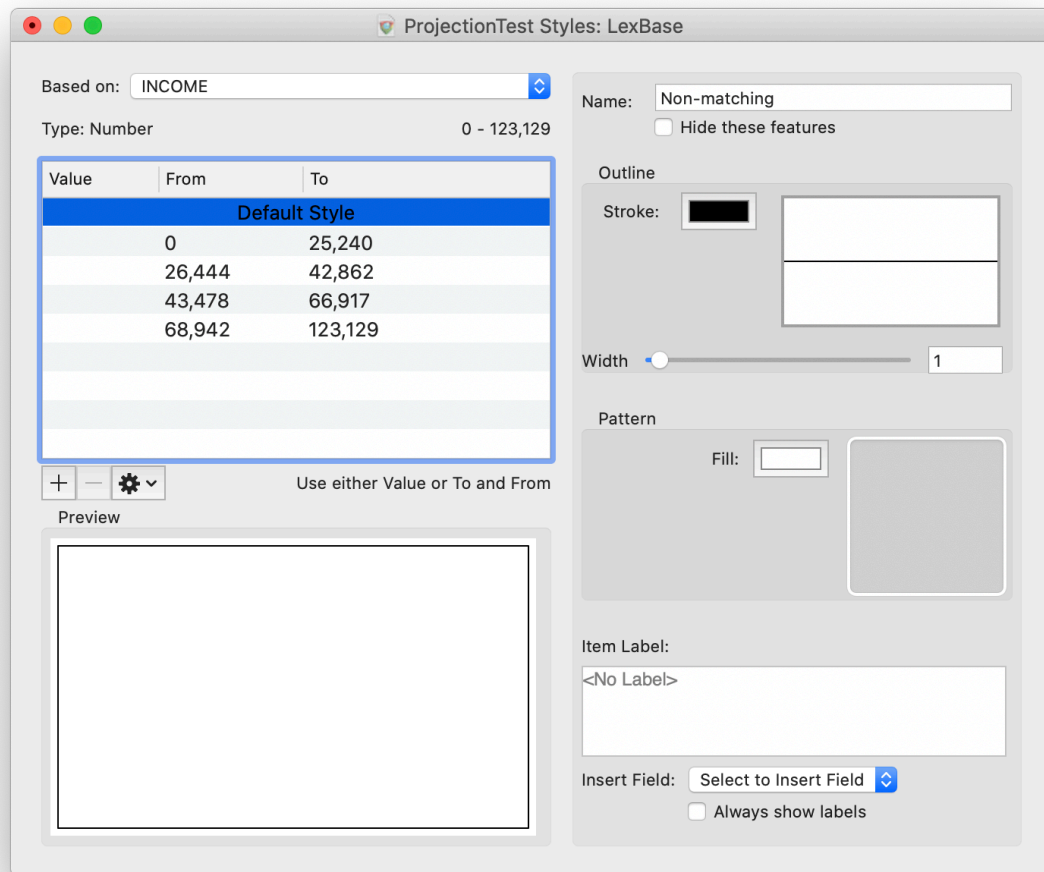

Cartographica has a sophisticated style system which provides significant control over how data is shown on the screen and in printed output.

Styles are assigned and manipulated for each layer individually.

6.1 Opening the Style Editor

How to open a **Style Editor** window for any layer.

1. Select the desired layer in the Layer Stack
2. Do one of the following:
 - Double-click on the layer name
 - Click on the **Styles...** button at the bottom of the Layer Stack
 - Choose **Layer > Show Layer Styles**
3. At this point, you should have an appropriate **Style Editor** visible.

Vector Style Editor Window

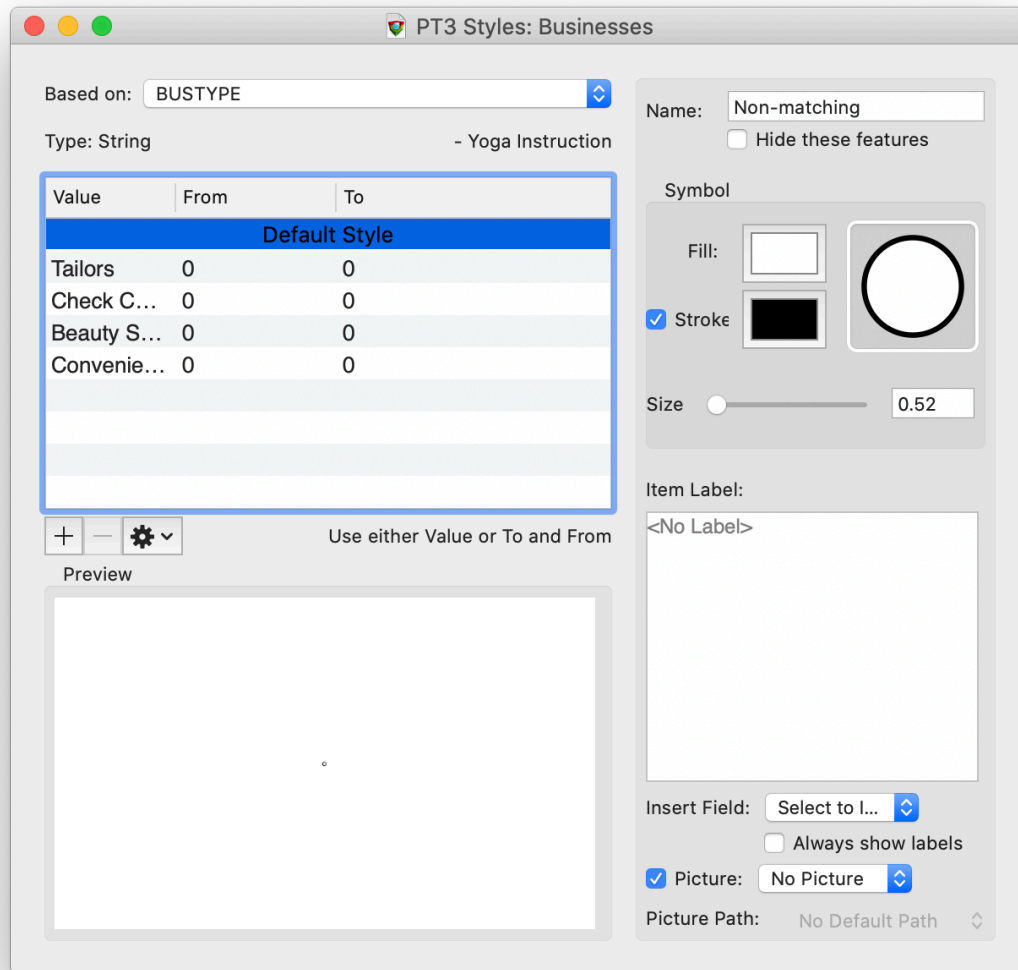

6.2 Styling Vector Layers

Styles in Cartographica are a very powerful mechanism for changing the presentation of your map. By using the values of data in the features, Cartographica can create thematic maps without requiring manual intervention in every step of the process.

When Cartographica prepares to draw a particular feature, it first evaluates the style, as defined in the layer's Style Window, to determine if the feature qualifies for a particular style variation, or if it is to be drawn with the Default Style. For layers where you desire all features in the layer to look the same, use only the default style and all features will be drawn the same.

Vector styles share many traits, although each different type of feature (lines, polygons, and points) have some unique attributes and slight variations in how the standard attributes are applied.

For all style manipulation, work begins in the Style Window.

Example Vector Style Window

The style window is divided into three primary areas:

- The upper left portion of the window contains the Style List, which is used to discriminate between styles in a style set. All layer styles can either be comprised of a single style (in this case, referred to as the Default Style) or multiple styles. This will be covered later in [Complex Styles](#).
- The right side of the window is the Appearance pane and it determines how each feature in a particular style looks. This includes the label, marker, lines, colors, and naming.
- The lower left portion of the window is a Preview of the style you are currently working on. In the case of multi-style style sets, the selection in the Style List determines which style is shown in the Preview.

Since many of the elements of the Appearance pane are common to every feature type, we will examine what each element represents and how it is used, going from the top to the bottom.

- **Name** is used in the **Map Legend** and other areas of the software to represent this particular style in a style set. The contents of this field are used as the name of the style in the legend, when multiple styles are shown. If you leave the Name field empty, Cartographica will create defaults based on the values that comprise the style's range.
- The color wells are used to adjust the color of individual elements. Their use varies based on the type of features represented by the layer, and by the element that is being styled. Color wells function as drop targets and bring up the color picker when they are clicked on, allowing you to choose colors using the standard mechanisms available to all Macintosh software.
- **Size** fields are denoted by a slider and a text area and allow you to change size parameters, such as line width, pattern size, or symbol size. The slider and the box both provide the same control, and you can use them interchangeably.
- **Item Label** and **Insert Field** menus are used to determine what text should be placed next to the point, along the line, or inside the area. You can add text to the label by typing into the box, and references to fields can be added by placing the cursor where you want the field and then using the **Insert Field** pop-up menu to select the field you want added. A field marker (with the name of the field inside of a colored cell) will be placed at the cursor location. This is covered in depth in Styling Labels
- **Always show labels** determines if labels are always shown for this particular style, or whether the system should determine whether they should be visible or not. Generally, you should leave this unchecked for most styles, but if you have features whose labels you always want displayed, this box provides allows you to override that.
- **Symbol**, **Picture**, and **Picture Path** are only available when editing Point features, and so they will be covered in [Point Styles](#).

6.2.1 Point Styles

Point styles can be customized in many ways. The Size slider and box control the total size of the point item. Due to variations in particular symbol drawing techniques and different visual weights (which affect apparent size), it is often the case that symbols with the same size are similar, but not identical in size or area. This is to be expected. We have tried to keep the sizes consistent for all symbols created directly inside of Cartographica, but you may need to balance sizes a bit, especially when using custom picture- or font-based symbols or when using symbols of greatly differing weights.

For most Point symbols, the Stroke box and color well determine if the outline of the symbol is visible and the color of the symbol outline. Not surprisingly, the **Fill** color well determines the color which fills in the symbol. For some symbols, there is no fill area, and therefore the symbol's fill color does not matter and the stroke must be present for the symbol to draw. Examples of these in the built-in symbols are the cross and plus.

Although Cartographica may not ship with the variety of symbols of some other programs, the ability to import high-resolution symbols from a variety of places makes up for many missing symbols. To change a symbol, the **Symbol Well** is used as the dropping point for one of a variety of sources:

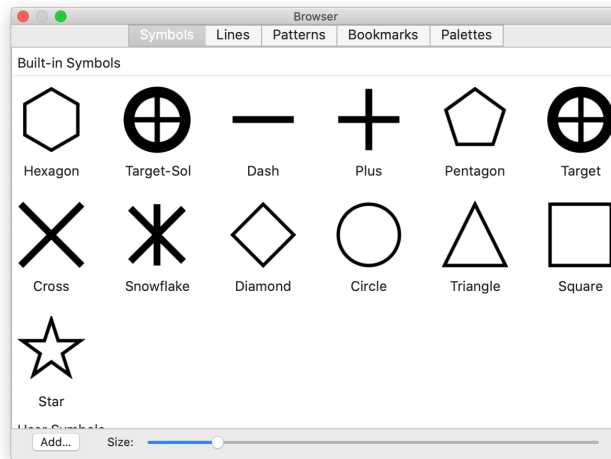

- The **Symbols** Browser window, which is the built-in repository for scalable symbols (pictured in [Symbol Browser Window](#)), contains a number of common symbols for use on maps which are simple, but highly scalable.
- Images from a variety of sources. Basically any image that you can get onto your Macintosh is usable as a symbol in Cartographica. This can be a graphic from a web page, something designed in illustrator, or a licensed piece of clip-art. PDF is the highest fidelity symbol format in Cartographica, because it will scale correctly with the symbol size

and the output medium. When an image symbol is used, Cartographica pays attention to the alpha channel for transparency, meaning that transparent-capable formats such as PNG are more desirable than JPEGs, as an example.

 When using images as symbols, the **Stroke** and **Fill** colors can seem to behave oddly. This is because, when checked, the **Stroke** will color anywhere in the image that is not transparent, and the **Fill** will not be used. For graphics that have transparency, this can have the desirable effect of being able to color the parts of the image with color. However, for graphics that contain black and white colors (for example), it has the surprising effect of coloring the entire symbol (white and black) with the stroke color. To turn off the color manipulation, just uncheck **Stroke**.

- The Macintosh Character Viewer. The Character Viewer is a standard part of OS X, which is made visible on the screen by checking the **Show Keyboard & Character Viewer** in menu bar option in the **Keyboard** preferences panel in System Preferences. Once this box is checked, you can bring up the window by choosing **Show Character Viewer** from the menu bar. Any character from the palette can be made into a Cartographica symbol just by dragging it into the Symbol Well. Among the available symbols in many standard fonts are: airplane, a variety of stars, and many more. Plus, cartographic symbol fonts are also available from a variety of commercial and non-commercial providers.
- Stylized text from any window. Although single-characters are often enough and our labeling system provides ample opportunity to provide static and variable text labeling, text from any window can also be used as a "symbol" for a point.

Besides symbols, Cartographica can also represent points with a picture stored on disk by using the Picture check box and field selector and optionally the **Picture Path** to specify the location of the referenced pictures. When using a picture to represent the points on the map, the **Picture** box must be selected and a field must be chosen in the pop-up menu. The picture field designates which column contains the file name of the referenced file, which can be a full or partial path name. A partial path name is resolved first by looking at the Picture Path and then by using the directory the layer (or map set for an internally-stored layer) is saved in as the default. When using a picture symbol, the **Image Viewer** will come up whenever a represented point is selected, showing a larger version of the picture (or a playable version of the movie, if the referenced data is a movie file).

Symbol Browser Window

Labels may also be added to point features, see [Labeling Features](#) for further information.

Setting the Symbol for a Point layer

1. Open the Style Editor for the desired layer
2. Click once in the Symbol well in order to bring up the Symbol Browser Window.
3. Choose a symbol from the **Symbol Browser Window** and drag it to the **Symbol** well.
4. Adjust **Point Size**, **Stroke**, and **Fill** as desired

Using a Font Character as a Symbol for a Point Layer

1. Open the Style Editor for the desired layer
2. Bring up a window containing the font character. Commonly this is done with the **Show Character Viewer** item from the menu bar (if you can't find it, you may need to turn it on in the **Keyboard System Preferences**)
3. Choose a symbol from the character viewer or other window and drag it to the **Symbol** well
4. Adjust **Point Size**, **Stroke**, and **Fill** as desired

Using an Image File as a Symbol for a Point Layer

1. Bring up a Finder window containing the symbol file

⚠ The file should be one of the standard image types understood by the MacOS X, such as: PDF, Adobe Illustrator, GIF, JPEG, PNG, etc.

2. Drag the file to the **Symbol** well
3. Adjust **Point Size**, **Stroke**, and **Fill** as desired

⚠ The effect of the **Stroke** and **Fill** on image symbols can be a bit strange. Generally, you will want to use the **Stroke** box and color only if you want to completely fill the symbol with the stroke color.

Using Pictures as a symbol

Before using pictures as a symbol, you must make sure that you have the picture files in a format that MacOS X understands, such as JPEG, GIF, or PNG. You must also know where those files are in relation to the **Picture Path** or the layer data.

These instructions assume that you already know where the pictures are and have a column that contains the partial or full path names to the picture files.

1. Open the Style Editor for the desired layer
2. Select the name of the column with the paths by using the **Picture** pop-up
3. If your photos are referred to by partial path names, you may need to select the **Picture Path** by using the pop-up menu
4. If you would like the pictures to show up in the map as the Point symbol, make sure the **Picture** box is checked

 To change the size of the displayed picture on the map, use the **Point Size** slider or box.

6.2.2 Line Styles

Line styles can be used to change the visual aspects of lines on a map. Some of the components for line styles should now be familiar to you, based on the point styles, but lines have some additional attributes.

Line styles are based on a line style template, which are dropped into the line style well in order to assign them to a style. In the example shown below, the Default Style for this line contains a line with thin black strokes, and a yellow fill. Not all lines will have both parameters, however they should all have a **Stroke** color, so that you can change the overall color of the line style. In some special cases, there are colors in the style that are not able to be changed through this window. If you are using one of these styles and find the need to change the color, look for another line style in the Lines tab of the Uber Browser.

The **Width** determines the width of the line, and in the case of a stroked line, the width of the stroke as well. The two are proportionate, and therefore the width is a scaling factor that operates equally on each of the components of the line.

Vector Styles Box (Lines)

Setting the Line Style

1. Open the Style Editor for the desired layer
2. Click on the line style well next to the color wells
The **Uber Browser** will appear with the **Lines** tab selected.
3. Choose a line style from and drag it to the line style well
The line style should change in the well, the preview, and on the map to reflect your choice.
4. Adjust **Point Size**, **Stroke**, and **Fill** as desired

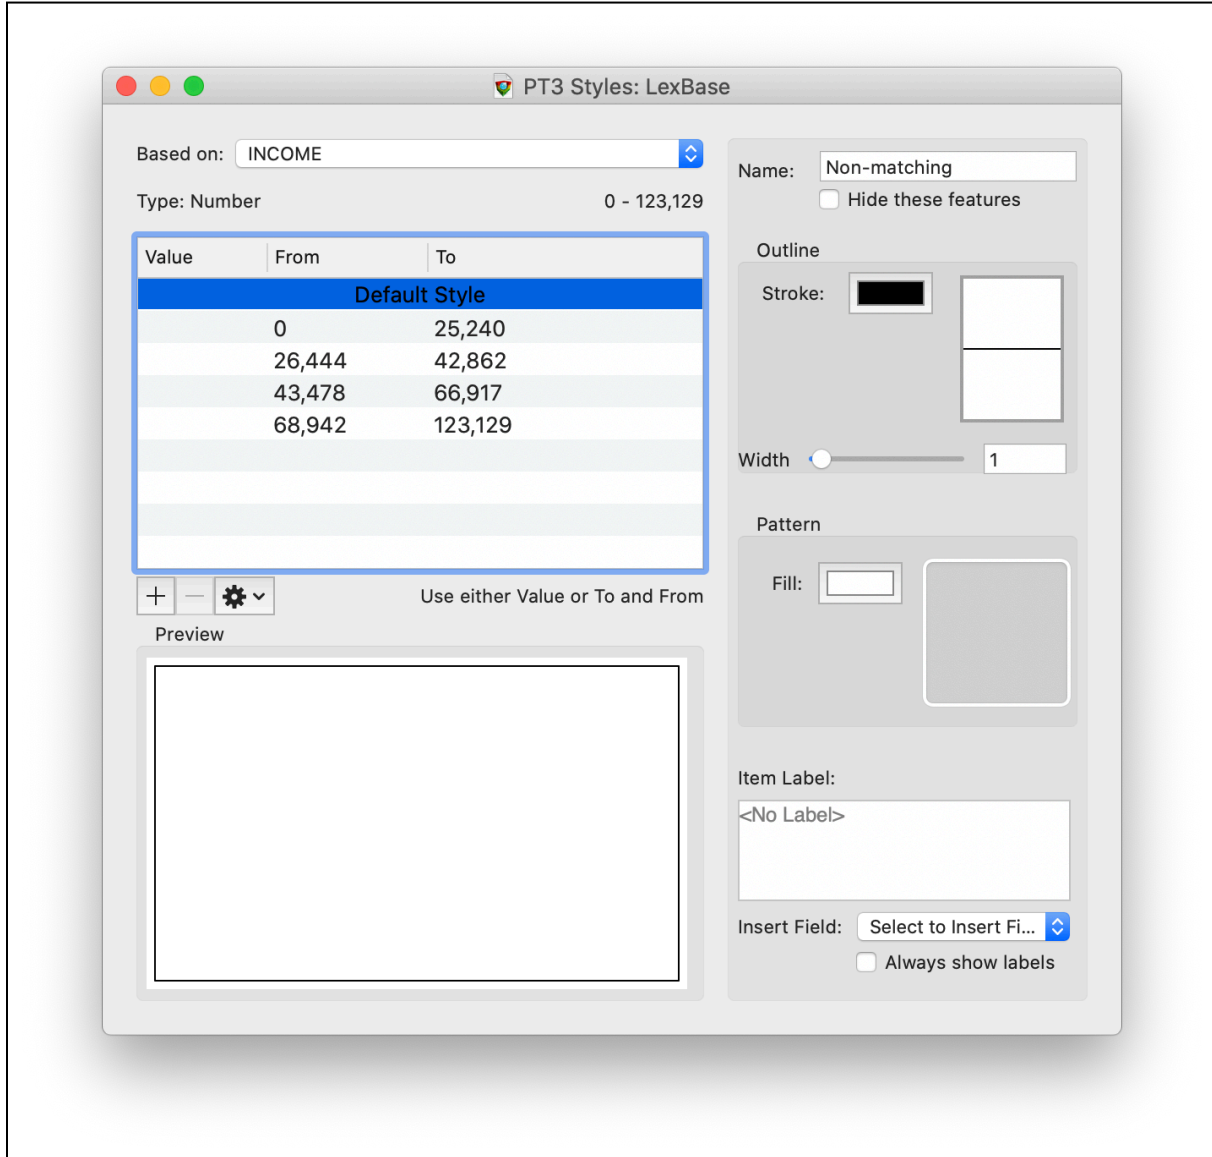

6.2.3 Polygon Styles

Polygon styles can be used to change the coloring, pattern, outline style, and labeling of polygon features on the map. You can leverage much of your knowledge from the line and point styles to use the polygon style window. In fact, the window is even set up to reflect this, with the **Outline** box in the top position (where the Line box appears for lines), and the **Pattern** box in the lower position (where the symbol box appears for points).

When a polygon is drawn, Cartographica uses the **Outline** information to draw the outline of the polygon, and the **Pattern** information to fill in the inside of the polygon.

The patterns in Cartographica work similarly to the Symbols in point layers. There are certain pre-defined patterns that come with Cartographica, and they are made up of black and transparent data, so that they can be scaled and colored easily. However, you can also use just about any image (including symbols from the symbol tab) as fill for polygon layers.

When a pattern is not in use, the pattern well is empty (as is shown below), and there is a **Fill** color well to determine the solid fill color to be used. When patterns are used, the pattern will appear in the pattern well and **Stroke** and **Size** controls will be added, to control the color of the stroke, and the pattern size, respectively.

Vector Styles Box (Polygon)

Setting an invisible line style

Sometimes it's necessary to have a polygon with no outer edge. In this case, you will need to remove the line to prevent it from drawing.

1. Open the Style Editor for the desired layer
2. Click on the line style well next to the color wells
The **Uber Browser** will appear with the Lines tab selected. (This can be ignored for now)

3. Switch back to the style window
You should find that the line style well is highlighted, indicating it has keyboard focus
4. Use the delete key on the keyboard to remove the line style
The line style should disappear from the well, the preview, and on the map to reflect your choice.

Setting an invisible fill color

Sometimes it's necessary to have a polygon with no visible fill color. In this case, you need to remove any pattern and set the fill color to transparent.

1. Open the Style Editor for the desired layer
2. Click on the pattern well next to the fill box
The **Uber Browser** will appear with the Patterns tab selected. (This can be ignored for now)
3. Switch back to the style window
You should find that the pattern well is highlighted, indicating it has keyboard focus
4. Use the delete key on the keyboard to remove the line style
Any pattern will disappear from the well, the preview, and on the map to reflect your choice.
5. Click on the **Fill** color well to select the fill color and bring up the Color window
6. Use the **opacity** slider to set the opacity of the fill color to 0%.
The well will be filled with a triangular symbol signifying you have a transparent color and color will disappear from the preview, and on the map to reflect your choice.

Using an Image File as a Fill Pattern

Open the Style Editor for the desired layer

1. Bring up a Finder window containing the image file for your pattern

 The file should be one of the standard image types understood by the MacOS X, such as: PDF, Adobe Illustrator, GIF, JPEG, PNG, etc. For best results for scaling, you will likely want to use a PDF file, although images will also tile.

2. Drag the file to the **Fill** well
3. Adjust **Size**, **Stroke**, and **Fill** as desired

 The effect of the **Stroke** and **Fill** on image fills can be a bit strange. Generally, you will want to use the **Stroke** box and color only if you want to completely fill the symbol with the stroke color.

6.2.4 Labeling Features

All styles can be labeled, providing a way to indicate the name or other attributes of a feature on the map.

Labels are among the most complex options in Cartographica due especially to the need to avoid clutter and collision when items are placed near each other. Although the particular algorithm cannot be

described in detail and is subject to some amount of change, here are some important points to understand about how Cartographica handles labels:

- All labels are drawn after all features are drawn and therefore labels show up "on top" of all features, including those features above the features that are being labeled. This prevents problems such as the label for a State (usually a polygon layer) being occluded by the point and label for a city in that state (usually a point layer positioned above the polygon layer so that the features are visible).
- Labels are evaluated in layer order, which is to say that the labels of layers at the bottom of the layer stack have a higher priority than those at the top of the stack.
- Within a layer, labels are evaluated in draw order, which is really not deterministic, and therefore there is not a good way to tell which labels in a layer will be drawn a priori.
- The best way to control labels is to only turn them on for items that are important for display purposes. This can be achieved by using a Complex Style (see [Complex Styles](#)) to separate the labeled and unlabeled items.
- When necessary, very complex labels can be made by using a Calculated Column (see) to create the contents of the field and referencing that calculated field in the label.
- Labels can have multiple lines, which are added by inserting a return in the Item Label box.
- Labels are controlled by the content of the **Item Label** box, shown in close-up in [Label Field Editor](#). Labels can contain text and fields and can be styled using one or more fonts and sizes. The example shown here is a simple label containing introductory text "Zip Code:" and the contents of the ZIP_LEFT field. In the **Item Label** box, the contents of a field are represented by a Field Marker, which is the name of the field surrounded by a colored oval.

Field Markers may be moved around through drag and drop and may be copied, pasted, and deleted.

Label Field Editor

Add a label to a style

1. Click in the **Item Label** box to move the text cursor there
2. Type the desired text in the box
3. Type text into the box to create an unchanging text label
Choose the desired field from the **Insert Field** pop-up menu to insert the field marker into the label.

6.2.5 Complex Styles

So far, we have been describing simple styles, which apply identically to every feature in a layer. However, it is often the case that some features in a layer deserve special attention. Examples of this include a layer that contains cities, some of which are state or country capitals, or a layer of roads that

contains both local roads and large highways. In each of these cases, some of the features in the layer are singled out for special attention.

Complex Styles are also used when attempting to show quantitative or qualitative attribute information graphically. For example, a polygon layer representing states could be colored differently based on population; similarly, the size of a city symbol in a point layer could vary based on population.

There are three primary controls for complex styles: the **Based on:** pop-up menu, which is used to determine which field is used to discriminate between the styles; the style list on the left side of the window above the Preview box, which displays the list of defined styles and provides for addition, deletion, etc.; and the **Hide features that don't match** check box, which determines whether the **Default Style** is used.

In complex styles, the **Based on:** pop-up menu determines which column of data is to be used for discriminating between the styles. Once the column is selected, use the table on the left of the window to determine the breaks for each style variant.

When using a string column to discriminate, you must use the **Value** column, which indicates an exact match between the value in the column and the one you define in the style here. When using a numeric column to discriminate, you may use either the **Value** column or the **From** and **To** columns. For the Value column, the data must still match exactly. When using the **From** and **To** columns, the value must be within the range specified. The **Distribute** button may be used to help create natural ranges based on a linear distribution over the range of the data in the selected layer.

Under **Based On** are 3 pieces of data that appear when a column name is selected. These are the field type (string, number, date), and the minimum and maximum values.

The table in the left of the window lists the values or ranges for each style in the style set. To change the appearance of the style, select it in the table at the left and then adjust the parameters on the right, using the techniques described previously for each feature type.

You may also select multiple styles at the same time, allowing simultaneous editing of items. This is useful, for example, when using different symbols, but wanting to change the size for each of them. In this case, select the desired styles and then change the size. The size will change, but the remainder of the appearance will remain unchanged.

Styles are added to the list by using the + and - or by **Edit > Duplicate** **Edit > Duplicate and Increment** button adds a new style by copying the default style. Each of the menu items provides a way to add an identical copy of the selected style to the list, with the **Edit > Duplicate and Increment** also increasing the **From** and **To** values.

When using quantitative information to discriminate between styles, it is often beneficial to have Cartographica assign breaks between the styles. The gear menu provides access to these functions, as outlined below:

Distribute With Equal Intervals	distributes the values of the Based On: field across all of the styles in the style list. For example, if the values range from 0-100 and you have 4 styles currently in the list, those styles are changed to range from 0-24,25-49,50-74, and 75-100 respectively. No other changes are made to the styles and the number of styles are not changed.
Distribute With Natural Breaks (Jenks)	distributes the values of the Based On: field using the Jenks natural breaks distribution method. This method will calculate the natural breaks that occur in the data set, based on attempting to determine where clusters of values exist. No other changes are made to the styles and the number of styles are not changed.
Distribute With Equal Count	distributes the values of the Based On: field by making each range contain an equal number of features. This is done using an increasing value, so the ranges will always be contiguous. For example: 5-10,11-20,21-30, etc.
Distribute With Equal Area	(available only for polygon layers): distributes the values of the Based On: field by making each range contain an equal area on the map, in the current CRS. This is done using an increasing value, so the ranges will always be contiguous.
Distribute With Quartile Distribution	distributes the values of the Based On: field into four (4) groups by making each range contain an equal number of features. This is done using an increasing value, so the ranges will always be contiguous. When applied to a style set, any existing styles will be used up to the fourth one, and all styles beyond the fourth will be removed.
Distribute With Quintile Distribution	distributes the values of the Based On: field into five (5) groups by making each range contain an equal number of features. This is done using an increasing value, so the ranges will always be contiguous. When applied to a style set, any existing styles will be used up to the fifth one, and all styles beyond the fifth will be removed.
Distribute Unique Values	distributes the values of the Based On: field into one group per value. This is mostly for use with string columns, although numeric columns with a small number of actual values can also be used. When applied to a style set, any existing styles will be used where possible, and all styles beyond those necessary will be removed.

All style information updates immediately, both in the preview window and in the map view, so the user should be able to drag the sliders and move around with the color picker until they have matched what they need.

Applying a palette of colors to a set of styles

It is often desirable to use a set of common colors for particular maps. Cartographica provides an easy way to take a color palette and apply it to the fill or stroke color of each element in a style list in turn. The result is a series of different colors, one for each style

1. Open the style window for the desired layer
2. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
3. Choose a color palette and drag it to the style list, dropping it when the cursor changes to the add cursor.

 To change the stroke color instead of the fill color, hold down the option key on the keyboard when you drop the palette

Temporarily disable all styles for a layer

This method disconnects the discrimination logic, leaving every feature in the layer at default. No other parameters are changed, so it can be used safely to "flatten" the appearance of a layer without actually changing it's style.

1. Open the style window for the desired layer
2. Change the **Based On:** value to **None**

 None of the other settings for the style set will be changed by doing this, so you can change back to your previous style settings just by returning the **Based On:** pop-up to its previous value.

Hiding Features

When using complex styles, there may be times where you want to remove items that match a particular criteria (or do not match any of the criteria) from the map. For this, Cartographica has the **Hide these Features** option to hide features which match a particular category. If you want to hide features that match a particular criteria, use the aforementioned mechanisms to create the criteria and then, with that item selected, check the **Hide these Features** box under the **Name**. If you want to hide all features which don't match some other category, follow the same step while you have the **Default Style** selected in the list.

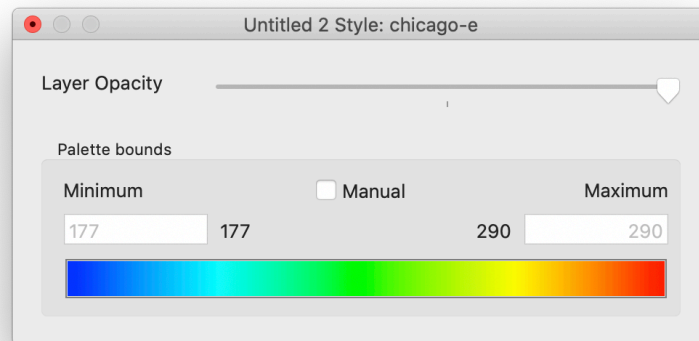

6.3 Styling Raster Layers

For raster layers, the styling is much simpler than for vector layers. Since the raster layer often contains detailed color data, there is no real need for a complex system as with vectors.

For some raster layers, their content is a representation of data instead of imagery. In these cases, Cartographica can be used to visually color the raster layer based on the values of data in the layer.

For both of these cases, you can adjust the opacity of the layer so that it may be placed above another layer, mixing some of the contents of the underlying layer with the contents of the overlaid layer.

Although a number of color palettes are included with Cartographica, see for more information about using and editing color palettes.

Example Raster Layer Style Window

6.3.1 Adjusting a Raster Layer's opacity

1. Select the layer in the layer stack
2. Choose **Layer > Show Layer Styles** to bring up the Raster Layer Style Window for this layer.
3. Drag the **Layer Opacity** slider to the desired opacity
The layer on the Map will update as you do this
4. Close the **Raster Layer Style** window

Changing a Raster Layer's palette

1. Select the layer in the layer stack
2. Choose **Layer > Show Layer Styles** to bring up the **Raster Layer Style** window for this layer.
3. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the **Palettes** tab of the Uber Browser.
4. Select a new palette from the list and drag it to the **Palettes** well in the **Raster Layer Style** Window
The layer color in the map should be updated immediately
5. Close the **Raster Layer Style** window

⚠ If you are working with a true-color image (one with component RGB), the palette well will not be available.

6.3.2 Concentrating the palette representation

In some cases, the entire range of the data is not useful for visualization. This can happen, for example when a data set contains mostly data in a small range, but has a few outlier data points that are the result of errors in data gathering. It can also happen when the interesting range is a small fraction of the total range of the data. Cartographica can visualize a smaller (or, in fact, larger) range of data values without having to modify the underlying data by constraining the application of the palette to a different range of values than those in the sample set. All values above the range and below the range are clamped to the highest and lowest values respectively.

Constraining palette range

1. Select the layer in the layer stack
2. Choose **Layer > Show Layer Styles** to bring up the **Raster Layer Style** window for this layer.
3. Check **Manual** to enable using a manual range for the palette
4. Type new values into the **Minimum** and **Maximum** boxes to determine the specific range
5. Close the **Raster Layer Style** window

Setting automatic palette range

1. Select the layer in the layer stack
2. Choose **Layer > Show Layer Styles** to bring up the **Raster Layer Style** window for this layer.
3. Uncheck **Manual** to use the automatic range
4. Close the **Raster Layer Style** window

6.4 Map Background Color

Cartographica can draw a background color behind all visible features in order to make the features stand out. Although this may be desirable for maps that are vector-based and have no styles, it can be distracting for choropleth maps.

You can change the background color for an individual map and also change it for all new maps going forward.

6.4.1 Changing the background color of a map

1. Choose **Edit > Show Colors** to bring up the Color Picker
2. Select or create a color of your choosing
3. Drag the color sample from the Color Picker to the Map View
4. Close the Color Picker

Changing the default background color for new maps

1. Choose **Cartographica > Preferences...** to bring up the **Cartographica Preferences** window
2. Click **Default Map Background Color** color well
The Color Picker will open
3. Select the color for the background
4. Close the Color Picker

7 Map Operations

7.1 Displaying the Scale

You can display the scale for the Map currently showing in the Map Window. To show the Scale box, choose **Map > Show scale**. A small Scale box appears in the lower right-hand corner of the Map window. Notice this Scale box gives the current scale, and changes as you zoom in and out of the map.

7.2 Trimming Maps

Trimming maps allows you to take a map that contains more information than is necessary for your task and make it smaller. You can trim a full map to a selection window that you make, or trim a map based on the smallest map possible containing all of the feature on a given map.

7.2.1 Trimming a Map to a layer's extent

1. Select the layer in the Layer Stack
2. Choose **Map > Trim Map to Extent of Selected Layer**
Cartographica will remove all data outside of the extent of the selected layer from the map on all layers

Trimming a Map to a feature's extent

1. Select the layer in the Layer Stack
2. Select one or more features to trim the map to
3. Choose **Map > Trim Map to Extent of Selected Features**
Cartographica will remove all data outside of the extent of the selected features from the map on all layers

Trimming a Map to a feature's area

1. Select the layer in the Layer Stack
2. Select one or more features to trim the map to
3. Choose **Map > Trim Map to Area of Selected Features**
Cartographica will remove all data not included within the area of the selected features

7.3 Changing the Projection of a Map

You can change the projection in the map window. This doesn't change the underlying data in any layer, it just coerces the data into that projection for display and output purposes. Any change you make here affects all of the Layers in the map and will persist until the change is made again using the same method.

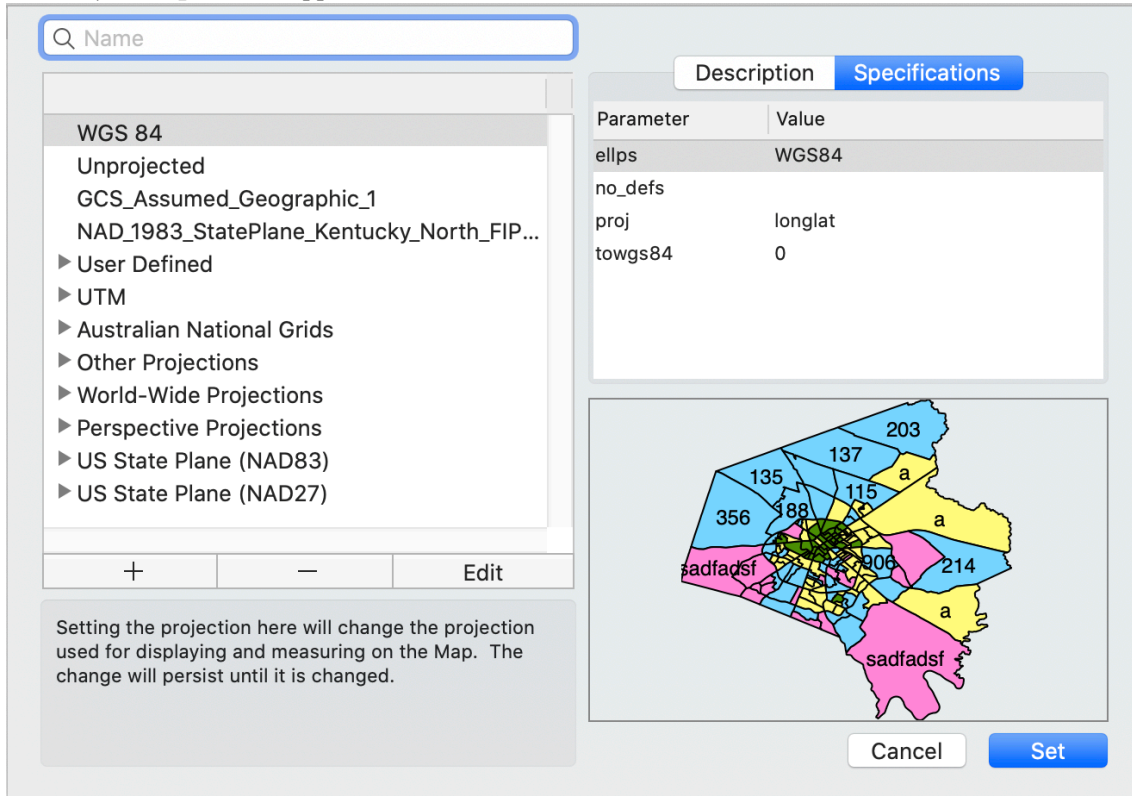

The projection of a map is a way of representing map data on a plane (a "flat" map) either on screen or on paper. All map projections distort the surface in some way. Depending on the purpose of the map, some distortions are acceptable and others are not; therefore different map projections exist in order to preserve some properties of the original shape in the flat map representation. You can choose from different projections to see which more accurately represent your data and which compromises are

most acceptable to you. You decide what the projection will be. Some representations of projections include the United Kingdom using the British Grid or Equal Area Projections giving maps of the United States that "curved" look or even using different map projections to give a 3D look to a map like you might see on a GPS display.

To change the target projection of a map:

1. **Map > Project Map.**

The **Project Map** window appears.

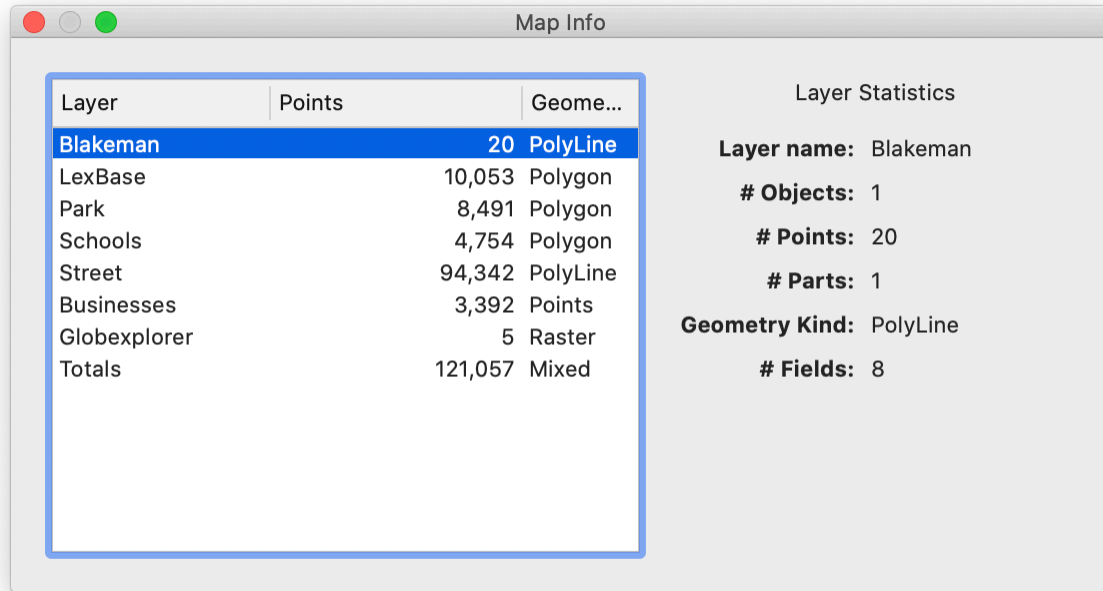

Project Map Window

- From the left side of the dialog, choose the map projection that best suits your needs. The **Description** box on the right will change depending which projection is selected. You can also click the **Specifications** tab to see additional details about the selected projection. Below this informational area there is a small preview area that gives a general orientation for the features of your map once the selected projection has been confirmed. You can use the search/filter box to find a particular projection (or group of projections) and narrow down your choices. As you type in the search box, the projections that do not match the search criteria are automatically removed, creating a smaller list from which to choose.
- Once you have the selected the projection that best suits your needs and most accurately represents the data you are attempting to display, click **Set**.

7.4 Showing Information About the Map

To show information about the map layers choose **Map > Map Info**.

The **Map Info** Window appears.

Map Info Window

This window shows the data about each layer in the map and also general data about the entire map such as number of points and what the geometry types of each of the points. When you click on the Layer in the left-side window, the data in the right-side window changes to show the information for the selected layer.

8 Analyzing Vector Data In Cartographica

8.1 Introduction to Cartographica Analysis

Cartographica's second calling, behind importing and displaying data, is analysis of that data. There are many options in the Tools menu for performing analysis and we will be adding more as time goes on.

There are two basic kinds of analysis functions, grouped by the type of resulting data. Analyses that result in a raster layer provide smooth visual outputs and selectable color maps, etc. Analyses that result in either new vector layers or modifications to existing vector layers provide high levels of scalability and are often more useful for further analysis. Some functions may be able to output either vector or raster data.

8.2 Making a Kernel Density Map (Raster)

Kernel Density Maps are a way to look at the relative density of point data as spread over an area. The Cartographica Kernel Density Map option uses a highly-accurate Kernel for its analysis. By default, the kernel density analysis uses a set of "reasonable" parameters, however an advanced version of the feature is available by holding down the Option key on your keyboard while selecting the menu item that allows you to change those defaults.

You can make a Kernel Density map on any point layer. This creates an analysis layer (basically a bitmap, at least visually, but it's actually a "cell" system where each "cell" contains the value for the area bounded by the rectangle the cell contains).

Depending on your particular data, you may find it helpful to either move this layer to the bottom of your layer stack, or use the Styles item to change the layer opacity to be more transparent.

To create a Kernel Density Map using the default parameters:

1. From the layer stack, select a single point layer in your mapset for which to analyze the density.
2. Select the Zoom level for the Kernel Density Map in the Map window by zooming in to the view you want. The default Kernel Density analysis is performed on the area in the Map View at time that you select the command.
3. Choose **Tools > Make Kernel Density Map**
After the analysis is complete, the graphical map will be added as a layer to the mapset.

Example Kernel Density Map

To create a Kernel Density Map specifying the precise parameters:

1. From the layer stack, select a single point layer in your mapset from which to analyze the density.
2. Select the Zoom level for the Kernel Density Map in the **Map** window by zooming in to the view you want.
3. Hold the Option key and choose **Tools > Make Kernel Density Map...**

The **Kernel Density Map Options** window appears.

Target Layer: Businesses

Grid Parameters

X Cell Count: Width: degree

Y Cell Count: Height: degree

☒ Keep Proportionate

Fit grid to: ☐ Layer bounds ☒ Map bounds ☐ Visible Map area

Kernel:

Intensity:

Weight:

Bandwidth: k:

Kernel Density Map Options Window

Select the options for this analysis:

- **Target Layer** is the point layer to be analyzed.
- **X Cell Count**, **Y Cell Count**, **Width**, and **Height** provide a way to change the number (and thus size, or vice versa) of the cells used in the calculation. The width and height parameters conform to whatever the target layer's projection is, so if the projection is in State Plane (feet), feet will be the size. Cartographica analyzes the field using a grid of cells spread evenly across the field. By setting the count of the grid cells, you can determine the coarseness of the grid that is used.

To change this, either choose the width and height in number of cells, or in map units (here in the example, it's in degrees, but if your map layer's CRS is set to feet or meters, the parameter will be in those units).

If the **Keep Proportionate** check box is checked, Cartographica will adjust the width to match the height you enter, and vice-versa. For a disproportionate grid, then uncheck the box.

- **Fit grid to** allows for adjustment of the coverage area of the grid to one of the following:

Layer Bounds	constrains to the data in the layer
Map Bounds	constrains to the entire map
Visible Map Area	constrains to the area currently shown on the map view (where this is useful if you want the KDM to go beyond the boundary of the current map to provide some context by means of a smooth drop-off)

- **Kernel** specifies the kernel used for the analysis

Normal (Gaussian)	Unbounded. Each data point contributes something to every cell
Quartic (or Spherical)	Bounded. Approximates the normal with a constant k.
Exponential (Negative)	Much more weight is given to the center points
Triangular (Conic)	Linear decay with distance
Uniform (Flat)	Bounded. Value is k or 0
Paraboloid/quadratic (Epanechnikov)	Bounded, more spread out than Quartic (or Spherical) and used in ArcGIS

Available Kernels

- **Intensity** and **Weight** allow you to assign columns in the layer from which these values are retrieved. Without changing these parameters, the defaults are to use an intensity and weight of 1.0, which gives each point equal weight. These two values are multiplied and then added into the cell for the map. Thus, a cell that contains a single point with a weight of 2 and an intensity of .5 has a value of 1. For example, if you have data that is a list of duck-blind positions with the number of ducks seen in a one hour period, you would set the intensity to the count and that would give you an idea where the ducks are concentrated.
- **Bandwidth** is the radius of the band that the point affects in cells and determines the decay of the value from the central point. If the bandwidth is set to 8, then little or no effect will be generated by the 8th cell from the point. If you set this number larger, the effect will spread out to a wider radius.
- **k** is a parameter specific to a particular kernel function. See Available Kernels for details.

4. Once you have made your selections click **Analyze...** and the Kernel Density Map is created and added to the map as a new analysis layer.

8.3 Making a Convex Hull

Convex Hulls are geometric shapes that represent a completely convex hull or wrap around a set of data. They are created using vector polygon layers. If you select multiple features, Cartographica will generate the Convex Hull around all of the features as a set. If you instead select a layer with no selected items, the entirety of the occupied layer will be used as points to create the hull.

This works with all geometries, except a single point selection.

8.3.1 Creating a convex hull

1. Select the Layer that contains the points to add to the Convex Hull.
2. Choose **Tools > Make Convex Hull for Selection**. Default parameters are used to create the graphic. The Convex Hull appears on the Map encompassing all of the points you selected in the Data View, or the entire layer if you have not chosen any more specific points.

Example Convex Hull

8.4 Creating Buffers around Map Features (Vector)

Buffers are a very common and useful tool employed for data analysis. In its simplest form, a buffer is an area created around a feature (point, line or polygon) which keeps the basic shape of the original feature, but expands the size of the feature by some amount.

Buffers are often used around points to create a survey area. For example, you might create a buffer of 500 ft radius around a set of points representing schools in order to analyze the number of banks within 500 ft of schools.

Under some circumstances, negative buffers (buffers which are inset from the border of a polygon) are used to determine internal information about a set of polygonal features. Negative buffers may not be used with points or lines.

VISUAL EXAMPLE

8.4.1 Create Buffers

Create a new polygon layer representing a buffer of a specified distance around the selected layer's features

1. Select the features you want to create the buffer around
2. Choose **Tools > Create Buffers**

The **Create Buffers** sheet appears.

Create Buffers Sheet

3. If you want to create buffers in the coordinate system of the original features instead of the map, check **Create buffers in original features' projections**. This is not a common operation, as it can cause the buffers to appear irregularly shaped.
4. Do one of the following:
 - Select the distance that the buffer is created around the features as a number (using the **Uniform Width** field). Units will be displayed to the right of the box and if the units are linear, it is possible to set the units using the pop-up menu next to the box.
 - Select the distance (radius) that the buffer is created around the features as a **Width by Column** to have the current value the specified column determine the radius.

 Cartographica currently expects this column size to be scaled to the units of the layer. In the case of latitude and longitude, that's degrees, in other cases commonly feet or meters. The units will be displayed, and if the units are linear, it will be possible to change them using the pop-up menu next to the **Uniform Width** box.

5. Check **Copy feature data to buffers** if you want each attribute of the feature being buffered to be copied to the resultant buffer.

6. Click **Buffer....**

Cartographica creates a buffer area around the points, lines, or polygons that are in the selection or selected layer and saves them into a new layer.

⚠ Very large and complex geometries with small buffer sizes can take a long time to resolve.

8.5 Counting Points in Polygons

You can also use Cartographica to count the number of points from the target layer that are entirely enclosed within each polygon in the base layer. In particular, this includes the ability to find out how many points are contained in a particular area.

8.5.1 Count points in polygons

1. Choose **Tools > Count Points in Polygons**.
The **Count Points in Polygons Options** sheet appears.

Count Points In Polygon Sheet

2. Select the layer containing the data you want counted from the **Count Points From** drop down menu.

⚠ Only point layers will be available

3. Enter a name for the new column in the **New Column Name** field.
4. Click **Count**.
The selected points are counted and appear in the data window in a column named as you specified.

8.6 Adding Data Columns

Cartographica contains a number of features to quickly analyze and add columns containing information about your geospatial data. We'll briefly touch on each mechanism and procedure to do these

8.6.1 Adding Coordinates Columns for Points to the layer

This function adds coordinate columns (X, Y, and optionally Z and M) from the selected point layer. These data are added to your data table. To add coordinates columns,

1. Select the target layer in the layer stack
2. Choose **Tools > Add Coordinates Columns**.

Adding an Area Column to the layer

1. Select the target layer in the layer stack
2. Choose **Tools > Add Area Column**.

Adding a Length Column to the Layer

1. Select the target layer in the layer stack
2. Choose **Tools > Add Length Column**.

You are adding a length column that displays the length (in layer units) of the lines in the line or polygon. It is important to note that complex features (polygon layers) have all of their lines summed total length of all line segments in the polygons, but are measured as their actual length, not as a string of points.

For example if you have a complex line which contains a line from San Francisco to Salt Lake and a line from St. Louis to Washington, DC, the length of that line is the sum of the two lines, not the total distance from San Francisco to DC stopping in Salt Lake and St. Louis.

For polygons, the data is the length of all line segments in each line. So a polygon with a hole (donut) will have a length equal to the length of the exterior border of the donut plus the length of the interior border of the donut.

Adding a Midpoint Coordinates Column to the Layer

1. Select the target layer in the layer stack
2. You can add the coordinates of the midpoints of selected line (only) layers. You are essentially adding a midX and midY column showing the midpoint of the lines contained in each feature.

To add a midpoint coordinates column, **Tools > Add Midpoint Coordinates Column**.

If used with complex lines (such as lines with a gap), the midpoint shown will be half-way along the total distance of the line. In the example used in Adding a Length Column, the "midpoint" will actually appear as east of St. Louis, since the line from San Francisco to Salt Lake City is shorter than the line from St. Louis to Washington, DC.

Adding a Centroid Coordinates Column to the layer

You can add columns for the coordinates of the centroids of the selected polygon layers (and only polygon layers). The centroid is the center of gravity of the polygon. If you have a unit square, the centroid will be at .5,.5. If that unit square has a hole that is off center, then it won't be. Note also that in the case of complex polygons or polygons with concavities, the centroid may be outside of the polygon. However, it is always within the extent of the complex polygon. This adds cenX and cenY columns to the selected layer.

1. Select the target layer in the layer stack
2. Choose **Tools > Add Centroid Coordinates Columns**.

Adding a Column showing the Distance to Nearest Feature

You can calculate the nearest distance between the points in a point layer and the features in another layer. This can be used to calculate nearest neighbor to objects in the same layer or nearest distance to points, lines, or edges of polygons.

- ⚠ It is not only possible, but often desirable to add distance to the nearest points in the same layer. In this case, you must be careful to change column names if you want to add any data columns from the source. Otherwise, you may overwrite the original data with the data from the nearest feature.

- ⚠ Distance to polygons is the distance to the nearest edge and does not treat specially the case of being "inside" of a polygon. So, if your point is 5 meters inside of a polygon, the distance will be 5 meters from the polygon, just as it would be if the point were 5 meters outside of the polygon.

1. Select the target layer in the layer stack
2. Choose **Tools > Add Distance to Nearest Feature**.

The **Distance to Nearest Feature** sheet appears, showing the **Target Layer** into which the distance is to be added.

Copy	Column	Copy Name
<input type="checkbox"/>	DATE_LIS	DATE_LIS
<input type="checkbox"/>	RECORD_O	RECORD_O
<input type="checkbox"/>	ROB2001	ROB2001
<input type="checkbox"/>	ROB2002	ROB2002
<input type="checkbox"/>	ROB2003	ROB2003

Distance to Nearest Feature Window

3. Choose the layer whose features you would like to measure to with the **Calculate Distance to** pop-up menu.
4. Enter a name for the new column in the **Distance Column** box.
5. Optionally, select columns to copy from the **Calculate distance to** layer to the **Target Layer** by checking **Copy** next to the column name and changing the resultant column name (if desired) by putting a new value in the **Copy Name** column.

- ⚠ Columns that exist in the **Target Layer** are used when copying data, so be careful to change the column name if you don't want to overwrite data in the existing layer.

6. Click **Add...** to create the column and perform the calculation.

8.7 Geocoding Addresses

Another form of analysis that Cartographica performs is Geocoding, or GEOgraphic enCODING of data that is not native GIS data. Although similar in some ways to the process of importing other data, there are two special kinds of data we will treat separately: addresses and photos.

Cartographica has two distinct, and powerful, address geocoding capabilities. Prior to version 1.2, Cartographica provided geocoding based on address information that was already in the map. This was usually street information received from a government agency or a data provider. More recent versions of Cartographica have also added the ability to geocode using third-party geocoding services. These services provide high-quality, constantly-updated geocoding capabilities for addresses in a large area of the world. Although it is easier to set up, there are reasons why you might not want to use it for geocoding. Some of these reasons include: historical geocoding, where the data that you are geocoding uses streets that no longer exist or have been realigned since the time of the original data collection.

 The MapBox Geocoder is available to users who have active maintenance or active subscription products. If your Cartographica license is a perpetual license and you need access to the MapBox Geocoder, you will need to have an active maintenance plan. Included geocoding services have limits on the number of addresses that can be geocoded without charge. The Bing Geocoder requires a Bing Maps access code. Cartographica no longer includes Bing Geocoding access as part of the subscription or maintenance.

8.7.1 MapBox Geocoding

Using the MapBox geocoder removes most of the configuration headache from the process of geocoding. In many cases, it is more up-to-date than files that you can obtain about the area that you are geocoding and it is certainly easier to configure.

Configuring MapBox Geocoder

1. Choose **Tools > Geocoder Options...**
2. Select **MapBox Geocoder** tab and click **OK**.
You are now ready to use the geocoder in this map.

8.7.2 Bing Geocoding

Using the Bing geocoder removes most of the configuration headache from the process of geocoding. In many cases, it is more up-to-date than files that you can obtain about the area that you are geocoding and it is certainly easier to configure.

Configuring Bing Geocoder

1. Choose **Tools > Geocoder Options...**

2. Select **Bing Geocoder** tab
3. Paste your Bing Maps key into the **Bing Maps Key** box and click **OK**.
You are now ready to use the geocoder in this map.

8.7.3 Internal Geocoding

Geocoding is a complex function and requires all the right data be in place to do it well. Cartographica has a powerful Geocoding capability, but to use it, you must gather data first. Most data is accurate to the last census update and may be more recent, based on the government's move to modernize and increase accuracy in the data or your commercial source. Keep in mind that if you are trying to geocode an old address, your accuracy may suffer if the data is too new, since some street realignments, renaming, renumbering, and removals may have changed the landscape since the address data was taken.

In comparison to the geocoding services, the Internal geocoding is much more strict in terms of how it interprets data. So, you should expect to use highly regularized data to match the TIGER/Line files; for example, "100 A St SE" in DC will not match "100 A St" using Tiger/Line data.

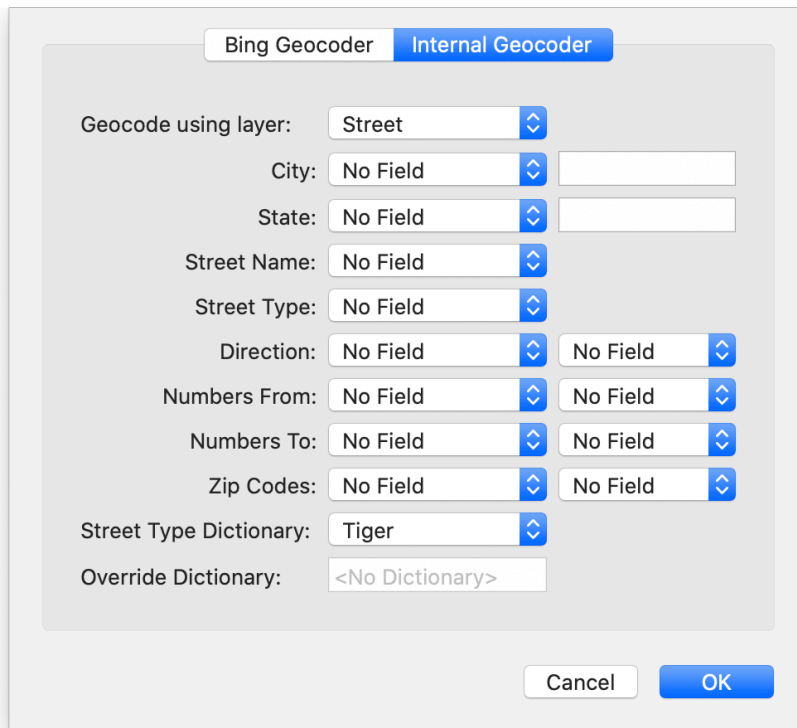

First, you need to figure out the area of your search. Generally speaking, you want to limit geocoding to a limited number of counties, to reduce the amount of work necessary on your computer. However, if you must do a large area, or if your area is undefined, there are geocoding services that can do bulk geocoding for a small fee.

Preparing to geocode with TIGER data

1. Locate the TIGER files on the Census Bureau web site. First, go to the [TIGER/Line Shapefiles](#) page, then select the particular year you're interested in. To use these files, you will need at least the *Edges* layer for the area that you're working with.
2. Locate the appropriate files on the server and download the state, county or counties that you are interested in using for geocoding. After unzipping the files, choose **File > Import Vector Data...** and then select the edges .shp file for import. This will import the edge data for that area.
3. If you need to geocode more than one census area, you may either merge the two layers into a single layer and use the new layer as the geocoding layer, or to run the geocoder twice, once with each layer selected.
4. The next step is to configure the geocoder. Choose **Tools > Geocoder Options....** If you are using standard TIGER/Line or Shapefiles, Cartographica should set up the geocoder automatically. In most cases, not only is the layer determined, but the field names are chosen as well. If you are using a file from a different source, or of a different vintage, you may need to set up the individual field names. At a minimum, Cartographica requires: Numbers From and Numbers To (for either side of the street or both), the Street Name, and Street Type (Rd, Ave, etc.). Each of the other entries (prefix and suffix, zip codes, state, and city) are optional but will increase the accuracy. In the case of City or State, you may type in value to match the City or State section of the address. However, it is not a requirement to use TIGER files for geocoding. The need is to have a minimum set of parameterized lines. Any line layer can be selected as the Geocoding layer.

Configuring Internal Geocoding

1. Choose **Tools > Geocoder Options**.
The **Geocoder Options** window appears.

Geocoder Options Window

2. From the **Geocode using layer** menu, select the layer that has the attributed lines in it.
3. Each of the geocoding fields in this dialog provides a more specific way to find the data.
For each field in the geocoding layer that you want to match to addresses, select an appropriate Geocoding Fields entry and choose the corresponding field. Generally, the more fields that you use, the more precise the geocoding will be. However, there are times when avoiding certain data fields is appropriate due to inaccurate data or the format of the original addresses.
The most important features are **Street Name**, **Street Type** (ave, rd, street, etc.) and **Numbers From** and **Numbers To** on the right and left sides of the street (indicated by the left and right columns). If you have these at a minimum, your data will probably geocode pretty well.
If you have **Zip Codes** for the left and right sides, those can help make things noticeably faster when working with large sets of lines.
4. If you have data for only one state and the data does not contain a state column, type in the state abbreviation in the State field to automatically exclude any addresses not in that state.
5. Once you have selected all of the geocoding options, click **OK**.
Now that you have set up geocoding, you can use it for the **File > Import Tabular Data...** or **File > Acquire Database Data...** features. Each of these have options to read the data as addresses and then geocode them.

8.7.4 Geocoding vCards

As an easy demonstration of Cartographica's geocoding abilities, you can geocode vCards (or addresses dragged from the Address Book).

Geocoding your address book

1. Set up the Geocoder options properly.
2. Drag any vCard onto a Map window
A new layer named **Geocoded** will be created with the address(es) from the vCard(s) you have copied.

8.8 Geocoding Photos

Geocoding photos is a way to take photos and place them on a map in Cartographica. Once these have been placed, they can be displayed as the point representation of a feature, or displayed when browsing the map by clicking on point.

There are two ways to geocode photos:

- import files that have already been coded with geospatial data (usually latitude and longitude and using the EXIF extensions to the JPEG file format)
- using the time code on digital photos to coordinate with information gathered by GPS devices to determine location

Cartographica currently supports both the import form and the timecoding form, imported either from files that you select. Photos originating from some cellular phones, such as the iPhone, and from some recently released cameras with GPS capabilities are the most likely sources of photos that are coded with location.

8.8.1 Importing encoded photos

This process is simple because the photos already contain all of the necessary information to put them on the map.

Importing photos coded with geospatial data

Add photos to a Map document from files with GPS data encoded in them

1. If you are bringing in photos from photo files, choose **Tools > Plot GPS Encoded Photos...** and select the picture files in the file window.
2. Choose **Tools > Plot GPS Encoded Files**
3. Select one or more files to import and plot into the existing map and click **Import**
Once Cartographica has loaded and coded the files, they will appear in a new layer on the map, with the location of each photo represented by a point feature.

8.8.2 Timecoding Photos

The process of importing photos using this method is a bit more involved due to the need to synchronize the clock information between the camera and the GPS device. If you expect to do this regularly, we suggest setting the camera's clock to the same time as the GPS whenever you turn on the camera, or at least once per day. You may also find it useful to set the time on the camera to GMT, as that is the native time of GPS and therefore requires the least amount of conversion.

Importing photos by matching photo times and GPS tracks

Add photos to a Map document from files by matching picture times with times and locations on a line layer (usually a GPS track)

Because the process is dependent upon the coordination between the camera and the GPS device, we describe the steps here from the beginning of the photo safari to the placement of the photos on the map.

1. Sync the time on your camera to the time on your GPS device.
Alternatively, record the difference between the times. This is easy if you can use your digital camera to take a picture of the time on your GPS when you start taking photos. However, if your GPS has no screen, then you should sync to GMT, which is the native time format for GPS data.
2. Take pictures.
3. Download the tracks from the GPS by doing one of the following:
 - Choose **File > Acquire GPS Data...** to bring data in directly from your GPS
 - Choose **File > Import Vector Data...** to bring in an existing GPX or other exported data file (such as those made by ClueTrust's [LoadMyTracks](#)).

If you are bringing in more than one track file (this might happen on multi-day trips, for example), you can merge the tracks together by selecting the tracks as a group in the Layer Stack and choose **Layer > Merge Selected Layers...**

4. If you are bringing in photos from photo files, choose **Tools > Timecode Photos...** and select the picture files in the file window.
5. Click **Import** and watch Cartographica plot your photos onto the map.
The result is a new point layer containing references to each of the photos placed on the map based on matching the time and the location.

Unlike geotagging software that writes information back to the file, Cartographica makes no modifications to the original photo files themselves, guaranteeing the safety and integrity of your image files.

When selecting a point in a layer with photos, you can see a full sized version of the photo by bringing up the **Image Viewer** by choosing **Window > Show Image Viewer**.

8.9 Cluster Analysis

Cartographica can perform basic and advanced cluster analysis based on a number of parameters. The overall algorithm used is DBSCAN, which is a progressive algorithm that is efficient and can find cluster patterns that elude other algorithms with a minimal amount of pre-configuration. This makes the algorithm particularly good for experimental or preliminary analysis, while still remaining effective for detailed analysis.

Cluster Analysis is for dealing with Point features, and cannot be used with other geometry types.

8.9.1 Performing a Cluster Analysis

1. Select the Layer that contains the points you want to cluster

2. Choose **Tools > Find Clusters...**
The **Find Clusters** sheet appears.

Find hot spots in point layer Businesses

Minimum Count

Distance (eps)

☒ Fixed Foot_US

☐ Average Nearest Neighbor Distance

☐ Expected Mean Distance

Confidence

Avg Distance: 195.846815832

NNI: 0.1700427772139529

Find Clusters sheet

Shortly after the sheet comes up, the Average Distance (average nearest distance for points in this layer) and NNI (the Nearest Neighbor Index—a value describing how likely it is that the data forms clusters; if the value is <1 it is likely clustered).

3. Adjust the **Minimum Count** to be the minimum number of points in a cluster
4. There are 3 distance functions that can be used in determining whether a point can be clustered with other points, of which you must choose one:
 - a. **Fixed** distance will be in the coordinate system of the *Map* (which is consistent with Cartographica analysis tools)
 - b. **Average Nearest Neighbor Distance** is based on the average nearest neighbor distance, and the value with the stepper indicates the number of standard deviations to include
 - c. **Expected Mean Distance** is based on a confidence interval based on the the expected density of the area
5. Finally, when you are satisfied with the parameters, click **Find**
The result layer will be added to your map as a new Polygon layer with a name based on the name of the layer to be analyzed

The techniques, and especially the **Expected Mean Distance** confidence intervals are modeled on those used by CrimeStat.

8.10 Spatial Join

Cartographica has a number of powerful facilities to provide for geospatial analysis and feature attribute propagation, among these is the powerful Spatial Join operation.

Spatial Joins are used to combine the data attributes of two or more layers. The Spatial Join operation creates a new layer that is a combination of attributes from Join and Target layers. The Spatial Join functions are akin to the Overlay functions except that the Spatial Join procedure does not change the geometry of the layers. Spatial Joins can be used for many different purposes and there are many options for determining how the join will be processed.

A Spatial Join can be performed on point, line, or polygon layers. The resulting vector layer will match the Selected layer's data format (i.e. point, line, or polygon). For example, if you select a polygon layer and then perform a Spatial Join (using an Intersect function) with a point layer as the Join layer, the output would be a polygon layer with attribute data joined from the point layer. In this case one attribute added to the polygon layer would be a count of the number of points that intersected with each polygon in the Selected layer.

The default Spatial Join option is the Intersection function, which will join two layers that overlap in space. In addition to the Intersection function there are 15 additional methods for performing Spatial Joins that can be used to fit various situations.

Spatial Join Operation	Description	Suitable Geometry
Intersecting	Selected layer feature intersects join layer feature at any point	Any and Any
Intersecting (3D)	Selected layer feature intersects join layer feature at any point (3D)	Any and Any
Within Distance	Selected layer feature is within distance of join layer feature at any point	Any and Any
Within Distance (3D)	Selected layer feature is within distance of join layer feature at any point (3D)	Any and Any
Contains	Selected layer feature contains any portion of the join layer feature (differs from intersection in that touching only at boundaries is excluded)	Polygons may contain Any Lines may contain lines or points Points may not be the selected layer.
Completely Contains	Selected layer feature contains all the join layer feature	Polygons may contain Any Lines may contain lines or points Points may not be the selected layer.

Spatial Join Operation	Description	Suitable Geometry
Within	<p>Selected layer feature is within if contained within the join layer feature</p> <p>Effectively Contains, but with the opposite result layer</p>	<p>Polygons may be within Polygons</p> <p>Lines may be within Lines</p> <p>Points may be within Lines or Polygons</p>
Completely Within	<p>Selected layer feature is within if completely contained within the join layer feature</p> <p>Effectively Completely Contains, but with the opposite result layer</p>	<p>Polygons may be within Polygons</p> <p>Lines may be within Lines</p> <p>Points may be within Lines or Polygons</p>
Within (Clementini)	<p>Selected layer feature contains all of the join layer feature, but the join layer must be at least partially within the body of the selected layer feature (i.e. cannot only be coincident with the edge).</p>	<p>Polygons may contain Any</p> <p>Lines may contain Lines or Points</p> <p>Points may not be the selected layer.</p>
Identical To	<p>Selected layer feature is identical to the join layer feature</p>	<p>Any may be identical to the same</p>
Touches Boundary	<p>Selected layer feature touches the join layer feature (but does not cross).</p>	<p>Any and Any</p>
Shares a line segment	<p>Selected layer feature shares a line segment with the join layer feature.</p>	<p>Polygon or Line and Polygon or Line</p>
Crossed by the Outline	<p>Selected layer feature is crossed by the outline of the join layer feature.</p>	<p>Polygon or Line and Polygon or Line</p>
Have Center Within	<p>Selected layer feature's center falls within the join layer feature. (Center for point is the point; for line is the midpoint; for multipoint or polygon is the centroid)</p>	<p>Any and Any</p>

Spatial Join Operation	Description	Suitable Geometry
Closest	The join layer feature closest to the selected layer feature.	Any and Any

Spatial Join Operations

8.10.1 Join Parameters

In addition to the [Spatial Join Operation](#), there are a few parameters that modify the behavior of the operations:

- **Maximum Distance** defines the maximum distance for the distance operations (**Within Distance**, **Within Distance (3D)** and **Closest**).
- **Distance Column Name** defines the column name of a column to contain the distance when used with any of the distance operations (if left blank, no distance will be stored).
- **One Feature per Match**, if checked, generates a new copy of the *Selected layer feature* for each match with a *Join Layer Feature*.
- **Discard Unmatched Features**, if checked, will not generate a *Selected layer feature* in the event that there is no match with the *Join Layer Feature*

8.10.2 Field Mapping

The **Field Mapping** box determines the mapping between the incoming fields (from both the Selected layer and the Join layer) as well as a few special calculated columns. The table shows the following columns, in order:

- **Operation** The operation to perform and store in this output column

Operation	Result
Copy	Matching feature's data will be copied
Ignore	No column will be created
Min	Minimum value of matching features' data
Max	Maximum value of matching features' data
First	Value of first matching feature's data
Last	Value of last matching feature's data
Sum	Sum of matching features' data
Average	Average of matching features' data

Operation	Result
Count	Count of matching features with data
Sigma	Sigma calculation of matching features' data

- **Layer** The original layer that the data comes from
- **Original Name** The name of the original column that the data comes from
- **Output Name** The name of the output column
- **Ratio** When checked, this indicates to calculate any value based on the ratio of the combined feature (only valid for the numeric operations). In particular, this checkbox will multiply the column value times the area (in case of the polygon) or length (in case of a line) in the join feature relative to the join features entire area or line. This is only relevant to the Intersection, Contains, Within operations for polygons and some boundary operations with lines.

 It is possible to create additional output columns for the same original field. To do this, select the desired field and choose **Duplicate This Mapping** from the pop-up menu by using ctrl-click. This can be handy when you need multiple numeric calculations on the same original column.

In addition to the fields from the Selected and Join layers, there are 3 specialized columns that are automatically created:

- **JOIN_FID** The feature ID of the join layer feature
- **TARGET_FID** The feature ID of the selected layer feature
- **Join_Count** The number of join features that matched this selected layer feature. If **One Feature per Match** is checked, then this should never be more than 1.

Using Spatial Join

1. Select the layer you want to use as the primary layer. This is the one from which features will be copied to the result layer.
2. Choose **Tools > Spatial Join...**
3. The **Spatial Join Window** will come up

Spatially join Businesses with:

Maximum Distance: degree

☐ One Feature per Match

☒ Discard Unmatched Features

Cancel Join

Spatial Join Window

4. Choose from one of the Spatial Join operations (discussed previously in [Spatial Join Operations](#))
5. Select the join layer in **Select Join Layer** box
6. Make desired changes to the output fields in the **Field Mapping** box
7. Click **Join**

When completed, a new layer will be added to your Map.

8.11 Overlay Operations Tool

Another tool in Cartographica for promulgating attributes between layers is the Overlay Operations tool. This tool, and its associated operations, provide a way to manipulate both the attributes and the geometry of layers. Each overlay operation has a different geometric effect, and can also contribute attributes to the target layer(s).

8.11.1 Overlay Operations

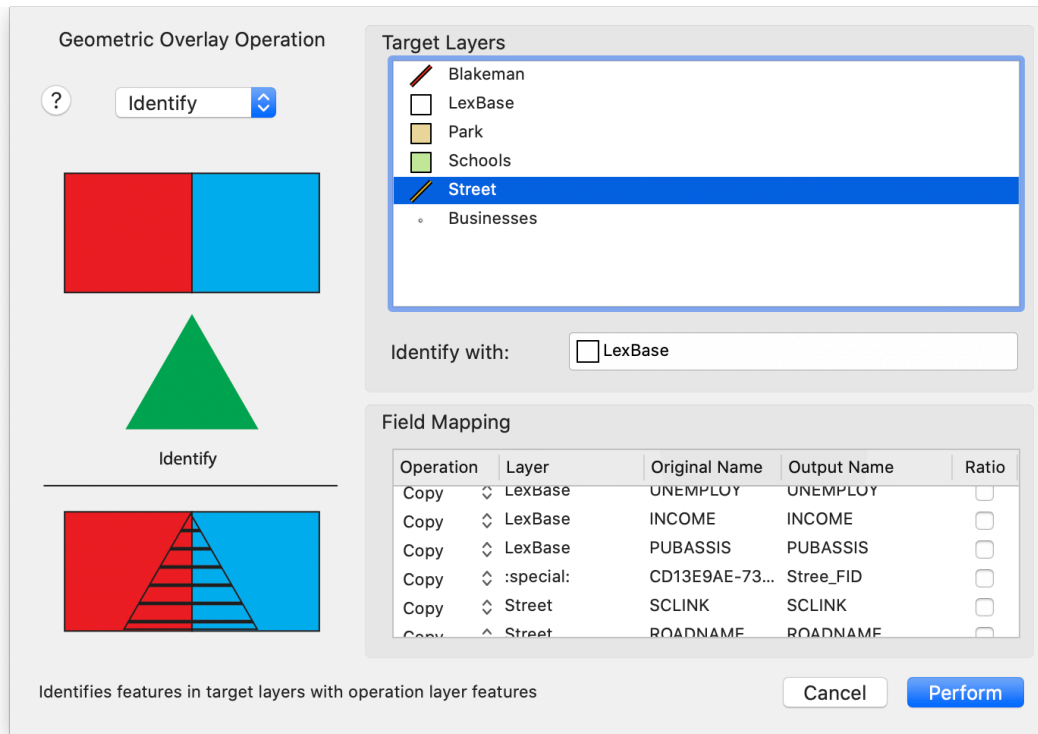

Operation	Description
Clip	Target layer features are clipped to the features in the clipping layer.

Operation	Description
Erase	Erase the target layer(s) with the erase layer. Portions in the target layers that match the erase layer are removed.
Intersect	Features that overlap with <i>all</i> target layers are maintained. Note that this differs from clipping in that features are removed if they aren't present in all layers.
Union	Features in all Target Layers are kept. Overlapping features are combined.
Difference	Features present in more than one layer are removed (possibly partially) to result in a layer that contains only the pieces of features that are only present in a single layer.
Update	Target layers are updated with geometry in the Update layer. Overlapping geometries will be replaced, and non-overlapping geometries (or parts thereof) will be retained.
Identify	Target layers are identified with the geometry in the Identify layer. Overlapping geometries will be updated to contain information from the Identify layer. Partially-overlapping geometries will be split into overlapping and non-overlapping parts.

Overlay Operations

Performing Overlay Operation

1. Choose **Tools > Overlay Operations...**
The Overlay Operation window appears

Overlay Operation Window

2. Choose your operation from the Operation menu (see [Overlay Operations table](#))
3. Select your target layer(s) in **Target Layers**
4. If appropriate, drag an operation layer from the **Target Layers** box to the operation box (which will be labeled according to the operation)
5. Adjust your **Field Mappings** as appropriate. Operation is identical to the [Spatial Join](#) Field Mapping section.
6. Click **Perform**

Once the operation is complete, new layers corresponding to the Target layers should appear in the *Layer Stack*

8.12 Creating Rasters from Point data

Cartographica contains a powerful analysis tool for generating Raster layers from vector point data. This tool can interpolate using a number of mechanisms in order to "fill in the gaps" of data based on a selection of algorithms. It should be noted that all of these algorithms are interpolations and you should consider the raster data to be a type of approximation, as opposed to accurate information. However, this tool can be useful for visualizing sparse data sets or data sets whose density varies.

The interpolation system uses the underlying GDAL grid system for its implementation.

For algorithms that use search ellipses, the angle of the ellipse rotation (counter clockwise, zero along the axis) is **Angle** and the radii of the ellipse are **Radius1** (along the X axis at **Angle** 0), and **Radius2** (along the Y axis at **Angle** 0).

Interpolation Algorithm	Overview	Parameters
Inverse distance to a power	<p>The inverse distance to a power method uses the weight and smoothing to calculate the grid value. If the ellipse radii (radius1 and radius2) are not set, then every point contributes to the value, based on the inverse of its distance to the grid node.</p> <p>If the ellipse radii are set and Max Points is set, at most that many of the nearest points within the radius are used.</p> <p>If the ellipse radii are set and Min Points is set, the grid node is considered empty if fewer than that many points are found</p>	Power Smoothing Radius1 Radius2 Angle Max Points Min Points
Inverse distance to a power with nearest neighbor searching	<p>The inverse distance to a power method uses the weight and smoothing to calculate the grid value.</p> <p>The circle radius (radius) should be set to a non-zero radius.</p> <p>If Max Points is set, at most that many of the nearest points within the radius are used.</p> <p>If Min Points is set, the grid node is considered empty if fewer than that many points are found.</p>	Power Smoothing Radius Max Points Min Points
Moving average	<p>The moving average uses a moving search ellipse in which all points are averaged when computing grid node values. Note, that it is essential to set search ellipse for moving average method.</p> <p>If Min Points is set, the grid node is considered empty if fewer than that many points are found.</p>	Radius1 Radius2 Angle Min Points
Nearest neighbor	<p>The Nearest Neighbor method takes on the value of the nearest neighbor within the ellipse defined by the Angle, Radius 1 (X axis at angle 0), and Radius 2 (Y axis at angle 0). If the Radius values are both 0, the entire point array is used.</p> <p>If no points are found within the ellipse, the grid node is considered empty.</p>	Radius1 Radius2 Angle
Linear interpolation	<p>The Linear method performs linear interpolation by computing a Delaunay triangulation of the point cloud, finding in which triangle of the triangulation the point is, and by doing linear interpolation from its barycentric coordinates within the triangle. If the point is not</p>	Radius

Interpolation Algorithm	Overview	Parameters
	<p>in any triangle, depending on the radius, the algorithm will use the value of the nearest point or the nodata value.</p> <p>If Radius is set to -1, the search distance is infinite.</p>	

Interpolate Point Data Algorithms

8.12.1 Using Interpolate Point Data

1. Select the layer you want to use as point source.

 By selecting features within the layer, you can limit the point source to just those features.

2. Choose **Tools > Interpolate Point Data...**
3. The **Interpolate Point Data Window** will come up

Interpolate Point Data Window

4. Choose from one of the Algorithms (discussed previously in [Interpolate Point Data Algorithms](#))
5. Make desired changes to the parameters
6. Click **Analyze**

When completed, a new layer will be added to your map.

9 Working With Raster Layers

Raster layers contain data a "coverage" of data that is sampled at equal intervals over an area. Often, these are satellite or orthophoto imagery (in which case, the reflected light from the surfaces is the data that was sampled), or LIDAR information (in which case it is the laser reflectivity that was sampled). In other cases, these data sets contain information from other sources, such as regular point samples of chemical concentration or regular samples of the height above a particular known level.

Styling the raster data was already covered in [Styling Raster Layers](#).

Cartographica 1.5 and newer contain raster analysis tools that can be used to transform raster data.

- [Merging Raster Layers](#)
- [Georeferencing Raster Layers \(side-by-side\)](#)
- [Georeferencing Raster Layers \(in-place tool\)](#)
- [Processing Height Rasters](#)
- [Creating Contours](#)

9.1 Merging Raster Layers

You can use Merge Raster Layers when working with raster data (such as satellite imagery from Landsat) that is split into separate layers for each color component. When using this data to show visible light, the layers (usually Red, Green, and Blue layers) must be merged into a single layer.

9.1.1 Merging Raster Layers Automatically

1. Select the Raster Layers you want to merge.
2. Choose **Tools > Merge Selected Raster Layers**.
Cartographica takes the selected layers in the order of the layer stack as Red, Green, Blue, and optionally alpha. Alpha is equivalent to transparency/opacity, where the minimum value is completely transparent, and the maximum value is completely opaque.
When merging layers manually, you have control over which layers to use, which can be helpful in re-arranging layers or in creating effects by using the same layer in more than one color band.

9.1.2 Merging Raster Layers manually

1. Select the Raster Layers you want to merge.
2. Hold down the Option key and choose **Tools > Merge Selected Raster Layers**
The **Merge Raster layers Options** dialog appears.

Merge Raster Layers Options Window

3. For each layer that you want to use, select a Raster Layer from the pop-up. Each layer may be selected zero or more times.
4. Check **Remove Used Layers** to delete the original layers once they have been merged. Leave it unchecked to leave the layers in place.

⚠ The original files on disk are not affected by the merging and will not be removed regardless of this setting.

5. Click **Merge** and the layers are merged and the new layer appears in the Layer stack.

9.2 Georeferencing Raster Layers (side-by-side)

This section covers the new side-by-side georeferencing tool, introduced in Cartographica 1.5.

There are times when raster data is delivered without spatial reference information. If you have an ungeoreferenced image, you will need to georeference it before it will show up correctly on the Map. In these cases, Cartographica can be used to adjust the images for their location, a process called Georeferencing.

⚠ Georeferencing is often a tedious task, and if there's a possibility that the spatial components exist for the raster files you are working with, you should seek these out.

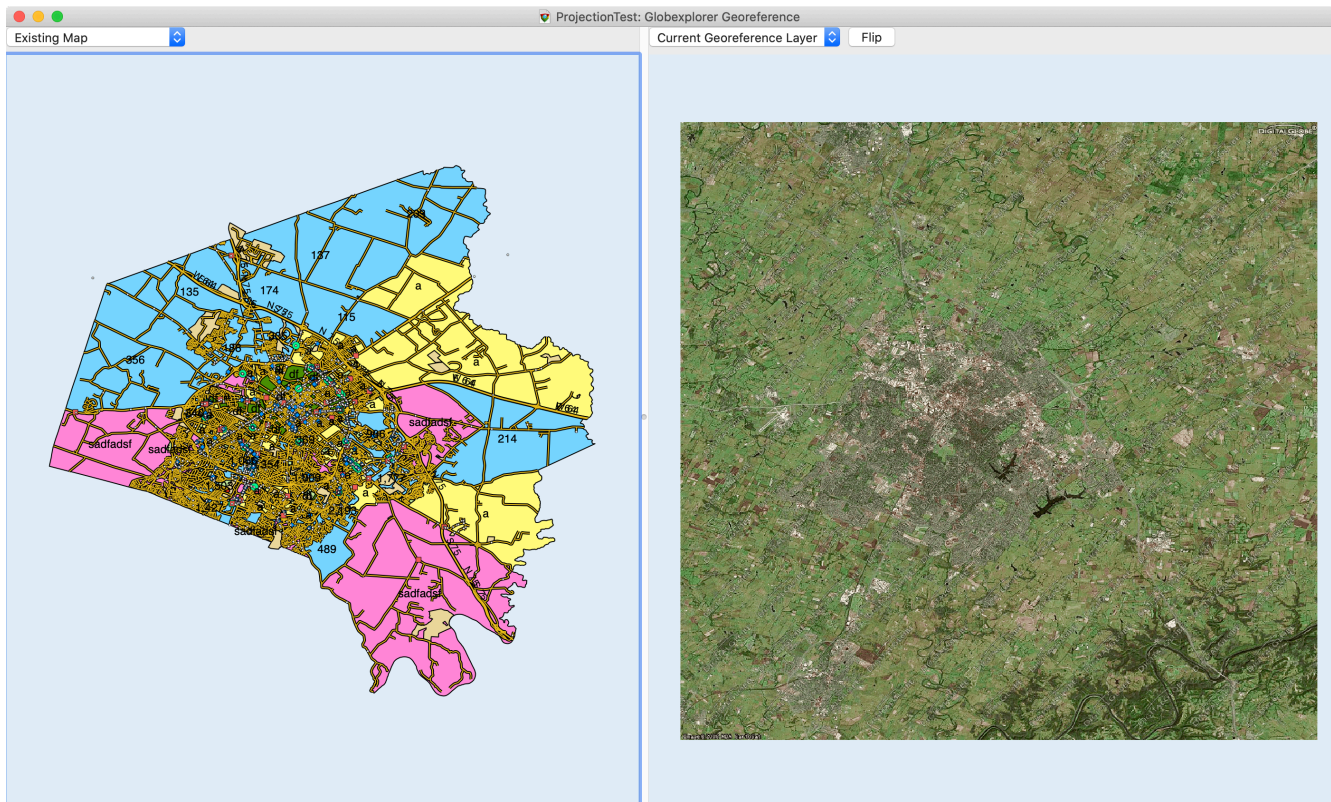

Cartographica has the ability to georeference raster data manually through the use of Ground Control Points or georeference matrices. Georeferencing involves telling Cartographica the location and size of the raster image relative to some known Coordinate Reference System (CRS), so that it can be displayed correctly along with other data. In order to appropriately georeference an image, you will need to have some form of reference layer, such as a vector map of the area or a live map.

In order to adjust georeferencing via a matrix, refer to the [Georeferencing Raster Layers \(in-place tool\)](#). That mechanism is mostly of use when you have knowledge of the exact location of an image as well as the size of an individual pixel in x and y directions. For most manual georeferencing, you will want to use this mechanism.

9.2.1 Georeferencing Raster Layers

With side-by-side Georeferencing, Cartographica displays two separate maps in the same window (see below). The left side of this window contains the reference map (the Mapset you are currently working with, initially without the layer being georeferenced), and the right side of the window contains the layer to be georeferenced.

The general process is to use the standard option-click on one side and then the other to match points. Once you have at least 4 (although preferably quite a few more, especially if the points are not in a large area), then the layer can be georeferenced.

Georeference Window

1. Begin with a Mapset into which you want to load the Raster imagery. This can be an empty Mapset, or one containing a multitude of layers. In general, you want to have at least one layer (so that you can set the Map Projection, which will be used as the projection for the georeference).

2. Use **File > Import Raster Data...** to import the desired Raster image into your Mapset. If it is not already georeferenced don't worry about any changes to the visuals in the Map, as they will only last until you have georeferenced the image. If it is distracting, or distorting your reference Mapset, you can uncheck the box next to the layer name to hide the layer.
3. Select the Raster layer to be georeferenced.
4. Choose **Tools > Georeference Image...** to begin the process, and the **Georeferencing** window will appear.
5. If the reference material in your map is sufficient for the task, you're good to move on to the next step. However, if you desire to use a Bing Maps tile reference, you can use the drop-down menu above the reference (left) pane, to change from **Existing Map** to **Bing Map**. By default, the Bing Map shows the map with roads. You can use the **Map Style** sub-menu to change between **Roads**, **Aerial Imagery** and **Aerial Imagery with Roads**.
6. You can use the tools in the **Map** menu to toggle between the **Zoom**, **Pan**, and **Identify** modes that work just like the same modes in a normal Map window.
7. Once you have located a suitable reference point, use the **Identify** mode (**Map > Identify**) and then control-click once on the left side to mark the reference location, and once on the right side to mark the image location. Once you've placed the markers on the map, they will be represented by a circle with a number atop it. The circle will be filled with white when the point pair is selected. Selecting a point on either side will select the corresponding point on the other side as well, as shown below:

Georeferencing with Points Selected

8. If necessary, you can click on an existing point and move it (either by dragging it, or by nudging it using the arrow keys on the keyboard).
9. Repeat these steps until you have a suitable count (>4) and distribution (representing most of the area) of reference points.
10. When this is complete, close the **Georeference** window to save the georeferencing information.

9.2.2 Modifying Existing Georeference

There are times when an existing georeference needs changing. Cartographica treats the georeference points as data which travels with the Mapset, so you can edit the georeference points in the future if necessary to adjust precision in certain areas.

1. Select the Raster layer in your Mapset to edit
2. Choose **Tools > Georeference Image...**
The **Georeferencing** window will appear.

3. Edit the reference points as described above.
4. When complete, close the **Georeferencing** window to save the georeference information.

9.2.3 Notes and Tips for Georeferencing

- If your image on the right shows upside down when you first begin, click on the **Flip** button to flip the image vertically.
- The Reference map menu on the left pane can be used to change between different reference maps while you perform the georeferencing. You may want to try flipping between a tiled reference, such as Bing and your existing Mapset.
- When using your current Mapset as a Reference map, you can also toggle the inclusion of the georeference layer itself by choosing **Show Georeference Layer** in the Reference map menu. This provides basically an in-situ preview.

9.3 Georeferencing Raster Layers (in-place tool)

This section covers the original Cartographica In-Place georeferencing tool. For most georeferencing needs, we suggest using the newer [Georeferencing Raster Layers \(side-by-side\)](#) tools, introduced in version 1.5.

There are times when raster data is delivered without spatial reference information. If you have an ungeoreferenced image, you will need to georeference it before it will show up correctly on the Map. In these cases, Cartographica can be used to adjust the images for their location, a process called Georeferencing.

 Georeferencing is always a difficult and tedious task, and if there's a possibility that the spatial components exist for the raster files you are working with, you should seek these out.

Cartographica has the ability to georeference raster data manually through the use of Ground Control Points or georeference matrices. Georeferencing involves telling Cartographica the location and size of the raster image relative to some known Coordinate Reference System (CRS), so that it can be displayed correctly along with other data. In order to appropriately georeference an image, you will need to have some form of reference layer, such as a vector map of the area or a live map.

9.3.1 Georeferencing Raster Layers

1. Make sure you have a reference layer loaded, unless you are manually setting the matrix or ground control points. A vector map of the area or a live map are often good choices for this.
2. Verify that your reference layer is included in the Map Extent. This will be the default for most Vector and Raster layers, but not for Live Map layers. Select the reference layer in the Layer Stack and make sure **Layer > Include in Map Extent** is checked.
3. Load your Raster layer by using drag-and-drop or **File > Import Raster Data...**
4. Click on the new Layer in the Layer Stack to select it
5. Choose **Layer > Set Layer's Projection** to choose the CRS in which the layer will be referenced (usually the same as the current map or the reference layer).

6. Zoom and pan the reference layer until you can see a location that is basically the same area as the area of the raster layer. Ignore for the time being the raster layer, since it likely will be very far away from its actual location to start with.
7. Choose **Edit > Georeference Image...** to begin the georeferencing
8. At this time, the Georeference panel should come up, providing control over the georeference process. By default, it starts in Ground Control Point mode, which allows you to drag the dots in order to match points in the reference layer.
9. Click **Fit Display**
At this time, the Raster image should be visible on the screen (although probably not in exactly the right place).
10. If your raster layer appears upside down, click **Flip Vertical** to correct that.

 On a machine with a trackpad, you can adjust the image's size and rotation using pinch and zoom and rotate.
Arrow keys can be used to "nudge" the position of the raster image

11. The mouse can be used to move the existing four corner GCPs so that they align with data in the reference layer. If you hold the Option (Alt) key down and click, you can create new GCP anywhere within the image. Option-click on the image to create the reference and drag to the point in the reference layer that represents that location. With more than 4 locations, a minimum of 7 GCPs is suggested for smooth representation.
12. When you are done with the georeferencing, choose **Edit > Georeference Image...** to end the edit

9.4 Processing Height Rasters

When working with Digital Elevation Model (or DEM) data, there is frequently the need to perform some analysis of the elevation data and how it relates to its surroundings. The **Tools > Process Height Raster...** command is intended to provide much of that capability in Cartographica. Based upon the [GDAL](#) libraries, Cartographica can perform a number of processing steps, including:

- Hillshade (shaded relief)
- Slope
- Aspect
- Color Relief
- Terrain Ruggedness Index (TRI)
- Terrain Position Index (TPI)
- Roughness

Cartographica performs these functions based on the selected layer or layers. As such, multiple raster layers can either be merged together and then analyzed, or they may be analyzed by selecting multiple layers and then choosing **Tools > Process Height Raster...**

9.4.1 Processing Height Raster Layers

1. Select the layer or layers to be processed in the *Layer Stack*
2. Choose **Tools > Process Height Raster...**
The [Process Height Raster](#) sheet will come up

Process height raster using:

Z factor ☐ Combined
 Scale ☐ Multidirectional
 Azimuth(°) ☐ Igor
 Altitude(°)

Process Height Raster Sheet

- Choose the type of processing you would like by selecting one of the tabs in the sheet
- If there are options in the window, you may fill those in and then press **Process** to perform the processing
A new layer will be created in the *Layer Stack* with the output of the processing

9.4.2 Supported Algorithms

All of the algorithms for these calculations come from recent versions of the GDAL libraries. Here we present a summary of the functionality and parameters, based on the documentation.

Hillshade

The *Hillshade* processor creates an 8-bit raster with a shaded relief effect. It is mostly useful for visualizing terrain. Adjustments can be made to the azimuth and altitude of the light source, and scaling information can be added to account for differences between the vertical and horizontal units.

- ⚠** Many of these algorithms expect that the X, Y and Z scales are the same in the original data. For data that is consistently in meters (x and y in a local projected coordinate system in meters, and the DEM data itself in meters), there's no need to adjust the scaling. However, in the case the source layer is in Lat/Long (for example), the scale will need to be set to 111120 if the DEM data are in meters and 370400 if they are in feet.

Z factor	Vertical exaggeration used to pre-multiply the elevation data. This may be necessary when trying to accentuate the height differences, for example for areas that are relatively flat.
Scale	Ratio of the <i>vertical</i> units to <i>horizontal</i> . (See note above)

Azimuth(°)	Azimuth of the light source, in degrees. 0 is from the top the raster image, 90 from the right side (East often). The default value is 315° is commonly used for shaded maps, and should be considered a standard.
Altitude(°)	Altitude of the light source, in degrees. 90 if the light comes directly above the DEM, 0° if it is raking light. The default value of 45° is commonly used for shaded maps.
Combined	Use a combination of oblique and slope shading. If not checked, it will use just oblique shading.
Multidirectional	Use Multidirectional shading, a combination of hillshading illuminated from 225°, 270°, 315° and 360°. Applies the formula from Multidirectional, oblique-weighted, shaded-relief image of the Island of Hawaii from the USGS.
Igor	Shading which attempts to minimize effects on other map features by rendering a "softer" hillshade. Uses the techniques covered in Igor's hillshading method from Maperitive.

Slope

Creates a 32-bit float raster with slope values as either percent or degrees. Where appropriate a no-data value of -9999 is used.

Scale	Ratio of the <i>vertical</i> units to <i>horizontal</i> . (See note above)
Slope as Percent	Checked if the output values should be as a percent, otherwise they are in degrees

Aspect

Creates a 32-bit float raster with values between 0° and 360° representing the azimuth that slopes are facing. The definition of the azimuth is such that:

Angle	Azimuth	Trigonometric
0°	Facing North	Facing East
90°	Facing East	Facing North

Angle	Azimuth	Trigonometric
180°	Facing South	Facing West
270°	Facing West	Facing South

This presumes that the raster input is North at the top when the data is processed). Where appropriate a no-data value of -9999 is used.

Trigonometric	Provide trigonometric angle instead of azimuth (see table above)
Zero for Flat	Return 0 for areas with a flat slope, instead of -9999

 By checking both of these options (Trigonometric and Zero for Flat), the aspect returned should be identical to the one from GRASS `r.slope.aspect`. Otherwise, its similar to the output of [Matthew Perry's aspect.cpp](#).

Color Relief

This process creates a 3-band (RGB) or 4-band (RGBA) raster with values that are computed from the elevation and from the color configuration, which provides a mapping from various elevation values to a corresponding desired color. Color blending is handled based on the settings in the Color Blending Mode table, and an optional Alpha channel can be added, which affects both blending and the use of exact color (in the case of exact color, non-matching colors are transparent).

Color Blending Mode	Effect
Smooth Blend	A proportionate blend between the nearest 2 colors is used
Nearest Color	The color in the Height/Color map which is nearest is used
Exact Match	Only exactly matching colors are set. All other values result in (0,0,0) or (0,0,0,0) if alpha is enabled

Specifying Height/Color Mapping in Color Relief Processing

Height/Color mapping can be provided either by manually entering items into the table or by loading color mapping files. The color mapping files are simple text files which have a list of heights and their corresponding color values. The values column (leftmost) contains the elevation value, which may be a floating point value, a percentage value (appended with %), or nv to indicate no data (no value). The

color columns may contain a textual color value (currently supported values are: white, black, red, green, blue, yellow, magenta, cyan, aqua, grey/gray, orange, brown, purple/violet and indigo), an RGB triple (red, green, blue), or an RGBA quad (red, green, blue, alpha). In the case of the multi-values, the values range from 0 to 255 and may be separated by spaces, commas, tabs, or colons (:). Finally, the absence of an alpha value denotes full opacity (255).

```
3500 white
2500 235:220:175
50% 190 185 135
700 240 250 150
0 50 180 50
nv 0 0 0 0
```

To specify Height/Color mapping manually:

1. Click + to add a row
2. Click in the *Height Level* of the new row and put in an elevation or %age
3. Click in the corresponding *Color Specifier* and put in a color name, or 3 or 4 values from 0-255 (3 for RGB, 4 for RGBA)
4. Value sets may be saved to a file by choosing **Color Sets > Save...** from the drop-down menu beneath the table.
5. Value sets may be loaded from a file by choosing **Color Sets > Load...** from the drop-down menu beneath the table.

Terrain Ruggedness Index (TRI)

This process creates a single-band raster with values computed based on the elevation and the mean difference between a central pixel and its surrounding cells. For details, see [Multiscale Terrain Analysis of Multibeam Bathymetry Data for Habitat Mapping on the Continental Slope](#).

Topographic Position Index (TPI)

This process creates a single-band raster with values computed based on the elevation and difference between a central pixel and the mean of its surrounding cells (also from [Multiscale Terrain Analysis of Multibeam Bathymetry Data for Habitat Mapping on the Continental Slope](#)).

Roughness

This process creates a single-band raster with values computed based on the elevation and the largest inter-cell difference of a central pixel and its surrounding cells (also from [Multiscale Terrain Analysis of Multibeam Bathymetry Data for Habitat Mapping on the Continental Slope](#)).

9.5 Creating Contours

When analyzing digital elevation data, it is frequently useful to be able to take elevation or height data from a raster source and create a vector representation of that for further analysis. In Cartographica, this is done using the Create Contours command.

9.5.1 Creating Contours from DEM

1. Select the DEM layer (or layers) from the *Layer Stack*
2. Choose **Tools > Create Contours...**

The **Create Contours** sheet will be displayed, showing the maximum and minimum heights on the left side, and providing two ways to create the contour levels on the right side.

Make contours for chattanooga-w

Maximum: 1651
Minimum: 158

Calculated Manual

Increment 170
Base 0

Cancel Create

Create Contours Window

3. For automatically calculated contours, enter your desired lowest contour in the **Base** field and the increments at which you want to space the contours in the **Increment** field. In the example above, the base of 0 and Increment of 170 will result in 10 contour lines at 0, 170, 340, 510, 680, 850, 1020, 1190, 1460, and 1630. Items above 1630 will be in the 1630 contour (since the range of this data is 158-1651).
4. To manually choose the contour levels, click **Manual** and then use the + and - buttons to add and remove contour levels.
5. Click **Create** to run the contour analysis
A new layer named with the name of the layer and *Contours* appended will be added to the *Layer Stack*

10 Editing Features

10.1 Editing and Adding Features

In some cases, you need to add geospatial data to a layer without exacting precision. Cartographica supports manual editing (and creation) of features in new and existing layers in order to facilitate this.

Feature editing is done in Edit Mode, where your changes are only temporary until you commit them. In edit mode, all of the layers (including the one containing the feature you are editing are "ghosted" behind the editing area so that you can still make out where in the coordinate space you are, but those features don't interfere with your navigation and editing.

When in edit mode, all navigational and zooming features are still available, so feel free to do things like Zoom To Feature or pan around in order to make your working canvas as appropriate as possible.

Individual points in features are shown using red dots. When these points are selected, the dots become hollow (have a white circle inside of them) to mark the selection. New points are inserted next to the currently selected point by holding down the Option key and clicking your mouse.

10.1.1 Editing an existing feature

1. Select the layer containing the feature you want to edit in the Layer Stack
2. Select the feature to edit in the Map View
3. Choose **Edit > Edit Selected Feature**.

(or double-click the feature when you are using the  icon in the Map pane)

The map pane goes into Edit mode. When you are in Edit mode, a partially transparent backdrop shows up behind the features you are editing to allow you to discern between what you're editing and the rest of the map. The color and opacity of this layer can be adjusted (see [Changing Edit Backdrop Color](#)). The original shape is also shown in the editing background. Here is an example of what the map window looks like in Edit mode.

Editing Map Feature

- Now you can change the geometry of the selected features. For example, you could move the location of a city or the path of a road.

There are certain restrictions placed on Cartographica while you are in Edit mode:

While in Edit mode:

- Holding the Option key on your keyboard and clicking your mouse adds a new point after the currently selected point.
 - Pressing the Delete key on the keyboard or choosing **Edit > Delete** will delete the selected point.
 - Multiple points may be selected at the same time and will move in unison.
 - Using the arrow keys will move the selected point in the appropriate direction (autorepeat is enabled).
 - To close a polygon, commit changes with it still open. Cartographica will add a terminal point at the same location as the origin.
 - All zoom controls function normally, except typing in the zoom box.
- To save (commit) your changes after editing, press Enter on the keyboard or choose **Edit > Edit Selected Feature** again.

To cancel your changes, press the Escape key on the keyboard.

Undo is handled separately when editing to preserve as much context as possible. So, when in edit mode, the undo/redo are used for each individual editing operation (like moving, deleting, or adding a point). Once you leave the edit mode (assuming you accepted the changes), these steps are forgotten but you will be able to undo the entire editing operation.

Once you have exited out of Edit mode and saved your changes, the changes are reflected in the **Point Data** window.

Adding a New Feature

- Select the layer where you want to add the feature in the Layer Stack

2. Choose **Edit > Add Feature**

If the selected layer has no content (and therefore isn't associated with a particular shape type), you are prompted for whether the new shape layer will be a point, line, or polygon.

The map pane goes into Edit mode just like when editing a feature. The same constraints apply to adding a feature as when editing a feature.

3. To add a new point to a feature in editing mode hold the option key on the keyboard and click to add the point.

4. To save your changes after editing, press Enter on the keyboard or choose **Edit > Edit Selected Feature** again.

To cancel your changes, press the Escape key on the keyboard.

Once you have saved your changes and exited out of Edit mode, the features you have added to the layer are viewable in the Point Data window.

Changing Edit Backdrop Color

1. Choose **Cartographica > Preferences...** to bring up the **Cartographica Preferences** window

2. Click **Edit Backdrop Color** color well

The Color Picker will open

3. Select the color for the editing backdrop

The **Opacity** slider determines how much of the background layer shows through to the editing view. To hide all other features, set **Opacity** to 100%. To disable the Edit Backdrop layer, set **Opacity** to 0%.

4. Close the Color Picker

Occasionally, geospatial data needs to be corrected by changing coordinates to be more accurate. In these cases, changing values directly in the point window might be more appropriate, especially when correcting obviously erroneous data.

Cartographica has the ability to change any existing point in any feature using the Point Data window.

10.1.2 Precision Editing Features in the Point window

1. Select the layer in the Layer Stack

2. Select the data you want to change (either in the Data View or Map View)

3. Choose **Window > Show Point Data**

The Point Data window appears showing the currently selected feature's geometry.

To change a point, click on a coordinate and type in a new coordinate value.

If you need to add or remove a point, select the line containing the point and use the + and - buttons to add or remove it. Of course, undo is available to undo whatever changes you have made.

Points are always edited in their original projection (CRS), so if your map is displayed in state plane, but the data being edited is in latitude and longitude, the editing will be in latitude and longitude unless use **Layer > Reproject Layer** the points in the layer.

10.2 Merging and Splitting Features

You can use the Merge Selected Features command to join geometries. This will work best for overlapping geometries, as they will result in a single part. If the parts are discontinuous (even if in a very small way), then they will be considered separate parts and you will end up with a multi-part geometry. There are two modes for this selection: intersection (features where any point is contained in the selection area) and containment (features where all points are contained in the selection area).

10.2.1 To merge selected features into one

1. Select the features you want to merge.
2. Choose **Edit > Merge Selected Features**

The features you have chosen are merged onto one feature containing each of your selections. The previous geometries will be removed.

Splitting a multi-part feature into separate features

1. Select the feature to split
2. Choose **Edit > Split Selected Features**

The feature you have chosen will be split into one new feature for each independent part in the existing feature. All feature data will be copied to each newly created feature. The original feature will be removed.

 In the case of complex polygons with islands and holes, the islands will be separated into new features and the holes will be assigned to the closest encompassing island.

11 Exporting Data

One of the benefits of having a desktop GIS is the ability to output data in a number of formats. Cartographica has extensive export capabilities to provide for just this type of operation. Generally, Cartographica can export entire Maps or just individual layers (or selected data within those layers). Which option is right for you depends on what you're trying to achieve.

11.1 Exporting Entire Maps

Cartographica can export Maps in a number of formats including (but not limited to):

- ESRI Shapefile
- GML
- KML
- MapInfo TAB
- MapInfo MIF
- Atlas BNA
- Adobe Illustrator

Cartographica exports the entire map either as a single file (if the format allows) or as one file per layer (if the format only handles single layers). You can also choose to not export invisible layers, to reduce file size and complexity.

11.1.1 To export an entire map

1. Choose **File > Export Map**
2. Select the export format from the **Export Format** menu
3. Check **Export Visible Layers Only** to limit the exported data to layers that are currently visible.
4. Choose a file name for the export and click **Save**

Warnings may show up in the export window to describe certain aspects of the exported data:

CRS can't be saved, map will be re-projected to native CRS	The target format doesn't support multiple CRS's and the CRS that you are currently using doesn't match it's format, so Cartographica will transform the data appropriately before writing it out.
Format doesn't support multiple geometries	A file will be created for each layer
Data fields won't be importable	data tables can't be exported and won't be importable as data into other programs
Some geometries won't be accurate	the selected file format doesn't have accurate ways to save all geometric types, so this format cannot be used to import data later. Cartographica will produce output that is as close as possible to what you see on the map display.

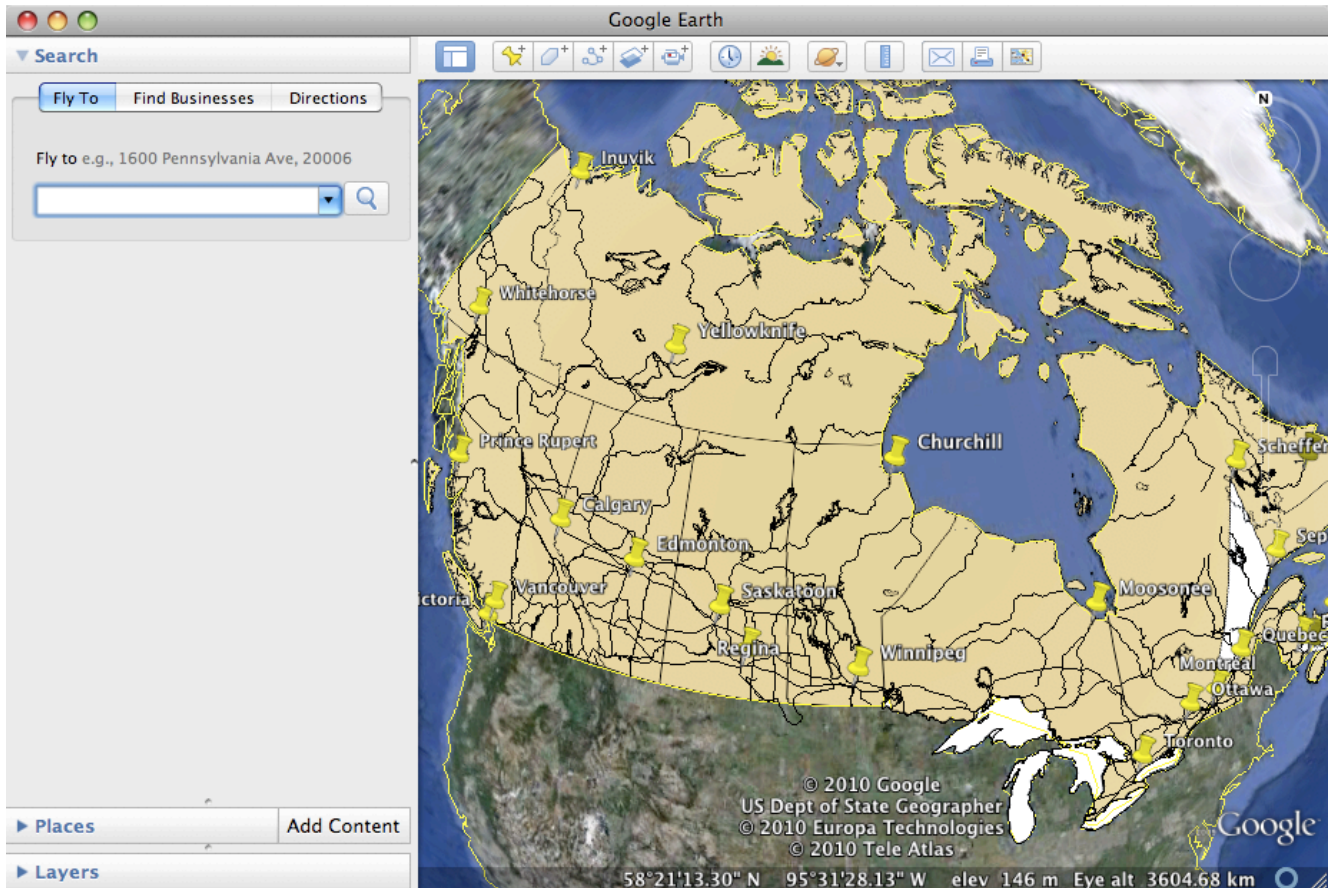

CRS can't be saved	the file format is device-independent and there is no place to indicate what format the data is in
Format does not support layers	Groups of features of specific types will be indistinguishable from other groups. There is support for multiple kinds of features, but not layers. As such, a single file will be created, but all polygons will be in a single polygon store, same for points and lines

11.1.2 Exporting Maps to KML

When exporting to KML, all data is exported as data in the layers. However, much of that data is not understood by Google Maps or Google Earth. In the future, it is possible that other programs will understand it. Cartographica exports the feature names based on either the default feature name, the label, or the feature ID. The data that shows up when you click on a feature in Google Earth or Google Maps will be either all data or just the data selected in the **Layer Info** window's **Pop-up** box.

Cartographica exports all layers in their current hidden/shown state unless **Export Visible Layers Only** is checked.

Here is a figure showing our example map and data of Canada exported to KML and then opened in Google Earth. You can see the convex hull in eastern Canada as well as all of the roads that existed in the original map in Cartographica.

Example Google Earth Export

Setting display fields for KML Export

Determine which fields are exported as part of the label when exporting to KML

1. Choose **Windows > Show Layer Info** to bring up the Layer Info window
2. Click on the **Fields** tab to show the field information
3. For each field that you would like to be displayed in the KML pop-up, check the **Popup** box.

⚠ This same box controls what information is displayed when **Map > Show Data Tooltips** is selected.

Setting the name of features for KML Export

Determine which field is used as the name attribute when exporting to KML

1. Choose **Windows > Show Layer Info** to bring up the Layer Info window
2. Click on the **Info** tab to show the general layer information

3. Choose the column name from the **Feature Name** pop-up

⚠ This same pop-up controls what the name of the feature when **Map > Show Data Tooltips** is selected.

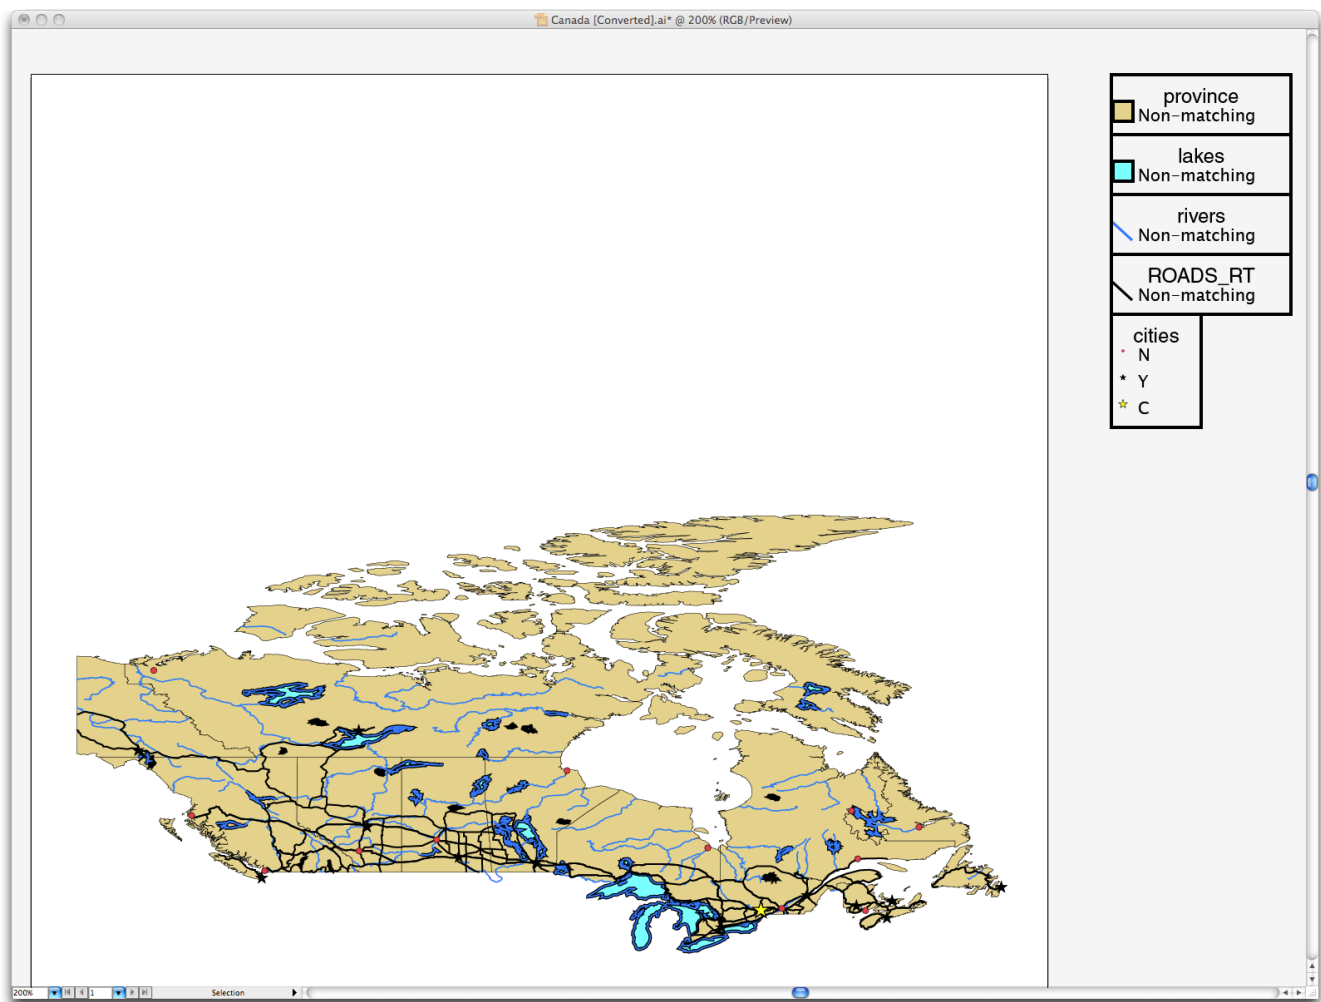

11.1.3 Exporting Maps to Adobe Illustrator

Exporting data to Adobe Illustrator is very similar to exporting to KML. All of the data is exported, but Illustrator can't always see it. The Features are named using the same technique as in KML above.

Cartographica exports each layer in the map to a separate layer in the Adobe Illustrator file. If the layer has labels, a separate Illustrator layer is exported just for the labels (allowing you to toggle these labels on or off as necessary after exporting). Finally, Cartographica exports a legend for each layer in the map, providing the basic style key for designers who use the Illustrator files.

When exporting to Illustrator, Cartographica also has the ability to embed the data for the layers into the Illustrator file, which is useful when working with third-party plugins, such as [Avenza MAPublisher](#). ClueTrust and Avenza have been working to make sure that maps exported from Cartographica and imported into Illustrator when using MAPublisher are the easy to manipulate and full of rich data. As such, when you check the **Include data in export** box while exporting to Illustrator, georeferencing, CRS (Projection) and column data is exported along with the feature data and the styles.

Here is an illustration of a map of Canada exported and then opened in Adobe Illustrator CS5.

Example Adobe Illustrator Export

11.2 Exporting Layers and Features

For some purposes, it is important to export only feature data, such as cases where you are sending data off for further processing or research using another GIS.

Cartographica exports individual features in ESRI®'s Shapefile format.

11.2.1 Exporting an individual layer or selection

1. Select the Layer that you want to export from the Layer Stack
2. Do one of the following:
 - Choose **File > Export Layer Features**
 - Choose **File > Export Selected Features** (if you want to export just the selection).
3. Optionally select the character set (UTF-8 will be the default.)

4. Enter a file name and click **Save**.

11.3 Exporting A Web Map

One unique feature of Cartographica is the ability to create a click-able web map from geospatial data. By using the layers of the map to create a web-compatible image file and then using the data in the data table, it can make each click-able area correspond to a link on the site or on another site. It can also provide roll-over text.

11.3.1 Creating a web map

Export a map for use with the web, complete with links to additional pages

1. Choose **File > Export Web Map**.
The Export Web Map sheet appears.

The screenshot shows the 'Export Web Map' dialog box. It has several dropdown menus and input fields. 'Selection Layer' is set to 'Park'. 'URL Column' is set to 'CLASS'. 'Label Column' is set to 'NAME'. 'File Format' is set to 'PNG'. 'Width' is set to '960' and 'Height' is set to '960'. There is a 'Quality (JPEG only)' slider. At the bottom, there are 'Cancel' and 'Export...' buttons.

Export Web Map Sheet

prompting for the following information

Selection Layer	The layer which is used to bound the selections. This must be a polygon layer.
URL Column	The column that contains the URL (if any) that should be the target of the link.
Label Column	The column that contains the label to be used for the target of the link.
File Format	The type of image file (JPEG, GIF, TIFF, or PNG) to create for the map.

Width and Height	The dimensions of the map to be produced.
Quality (JPEG Only)	If you have chosen JPEG as the file format export format, the Quality slider allows you to choose the level of quality for the output image. A lower quality also guarantees a smaller (byte-wise) image.

- Once you have set all of the information options, click **Export**.
Two files will be created for you: an image file and an HTML file in UTF-8. The HTML file contains the geometric information and the links which serve as the basis for a web page that will contain the map.

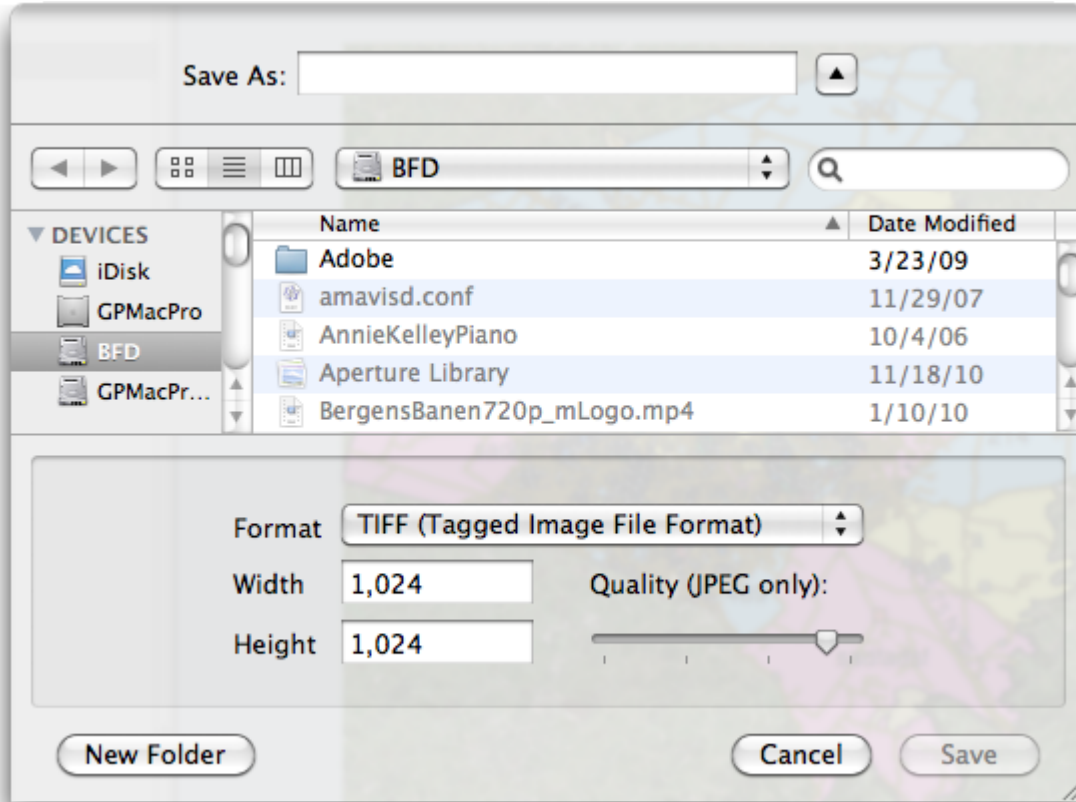

11.4 Exporting Maps as Pictures

Occasionally, you will need to take a map from Cartographica and produce an image file from it in order to include it in another document or use it in some other manner. Cartographica provides an easy mechanism to create georeferenced images that accurately portray the data on the Cartographica map at the time.

11.4.1 Export a Map as Picture

Export your map to a JPEG, TIFF, or PNG, complete with georeferencing information to view without a GIS

- Choose **File > Export Map As Picture...**
The Export Map As Picture sheet appears

Export Map As Picture Sheet

2. Choose an image format from the **Format** pop-up menu
3. Enter the desired width and height in the appropriate boxes
4. Click **Save**

The requested image file, along with a world file (usually tfw, jgw, or pgw) and a projection file (prj) will be created in the folder requested.

⚠ Some programs will understand the world files and some will import the prj files, but not necessarily all, so it is often desirable to use a standard CRS when exporting if you plan on importing the file into another spatially-aware program.

12 Producing Printed Output

Cartographica has two ways to create printed output: Quick Printing and Map Layout printing.

As one might expect, Quick Printing provides a quick way to create printed output for use either on the screen or in a PDF. It's no-frills and represents exactly what is currently on the screen.

Map Layout is much more sophisticated printing mechanism which uses a Map Layout document to define the way that the map will look on the printed page. In exchange for the additional complexity, Map Layout provides a way to print more than one map on a page and to add adornments, such as legends, scale, north arrows and more.

12.1 Quick Printing

Quick Printing is the easiest way to print a basic map. By choosing **File > Print** Cartographica will print a copy of the current map in as large a format as possible for whatever printer you are using. The larger the print area, the more well-defined the printout.

You can print different format maps by using the **File > Page Setup** command to set and change the size of the page to use as the destination for the Map Layout.

PDF maps can be created by using **File > Print** and then using the PDF menu in the **Print** window to save a PDF file. These files also pay attention to the **File > Page Setup** settings.

12.1.1 Quick-Printing the current map

1. With your map open, choose **File > Print...**
The standard Print window will come up with a preview area to the left.
2. Choose the image resolution from among the available options
3. If you want to print just the area that was visible in the map window, check **Print Visible Extent Only**
4. Change any other printer settings and print as you normally would.

12.2 Complex Map Layout

Cartographica has a second format for creating maps intended for production output. The Map Layout document can refer to any Cartographica Mapset file (or combination of files) and can contain maps, titling, scales, and legends. Map Layout documents contain a single page based on the Page Setup.

Cartographica supports scaling the view of the Map Layout so that it can be seen both in detail (zoomed in) and as an overview for large printouts (zoomed out). The size of the page is determined by the Page settings which can be changed by choosing **File > Page Setup**.

12.2.1 Create a new Map Layout

1. Choose **File > New Map Layout**
The new Map Layout window will appear, representing your newly created document

Map Layout Window

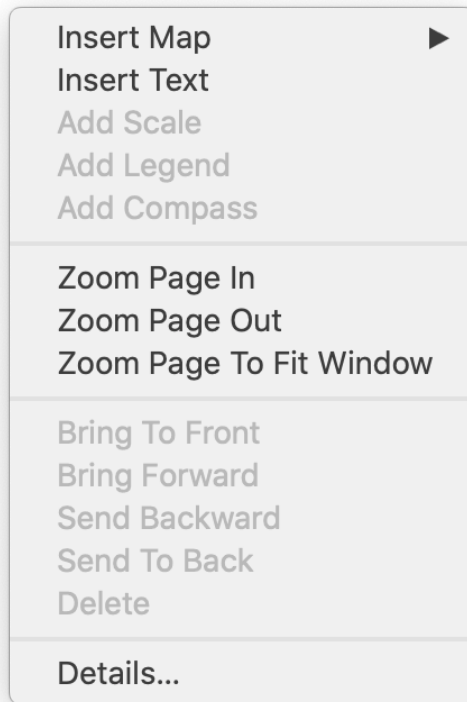

The easiest way to add new elements to the Map Layout window is to use the toolbar at the top of the window.

Map Layout Creation Tools

You can also add elements to the Map Layout window through contextual menus, otherwise known as right-clicks or Control-clicks. Control-clicking in most areas of the Map Layout will show a menu which will then provide you with options for editing the information or adding information.

When you open the Map Layout context menu by selecting the map, holding the Control key on the Keyboard and clicking your mouse, this is what the menu looks like.

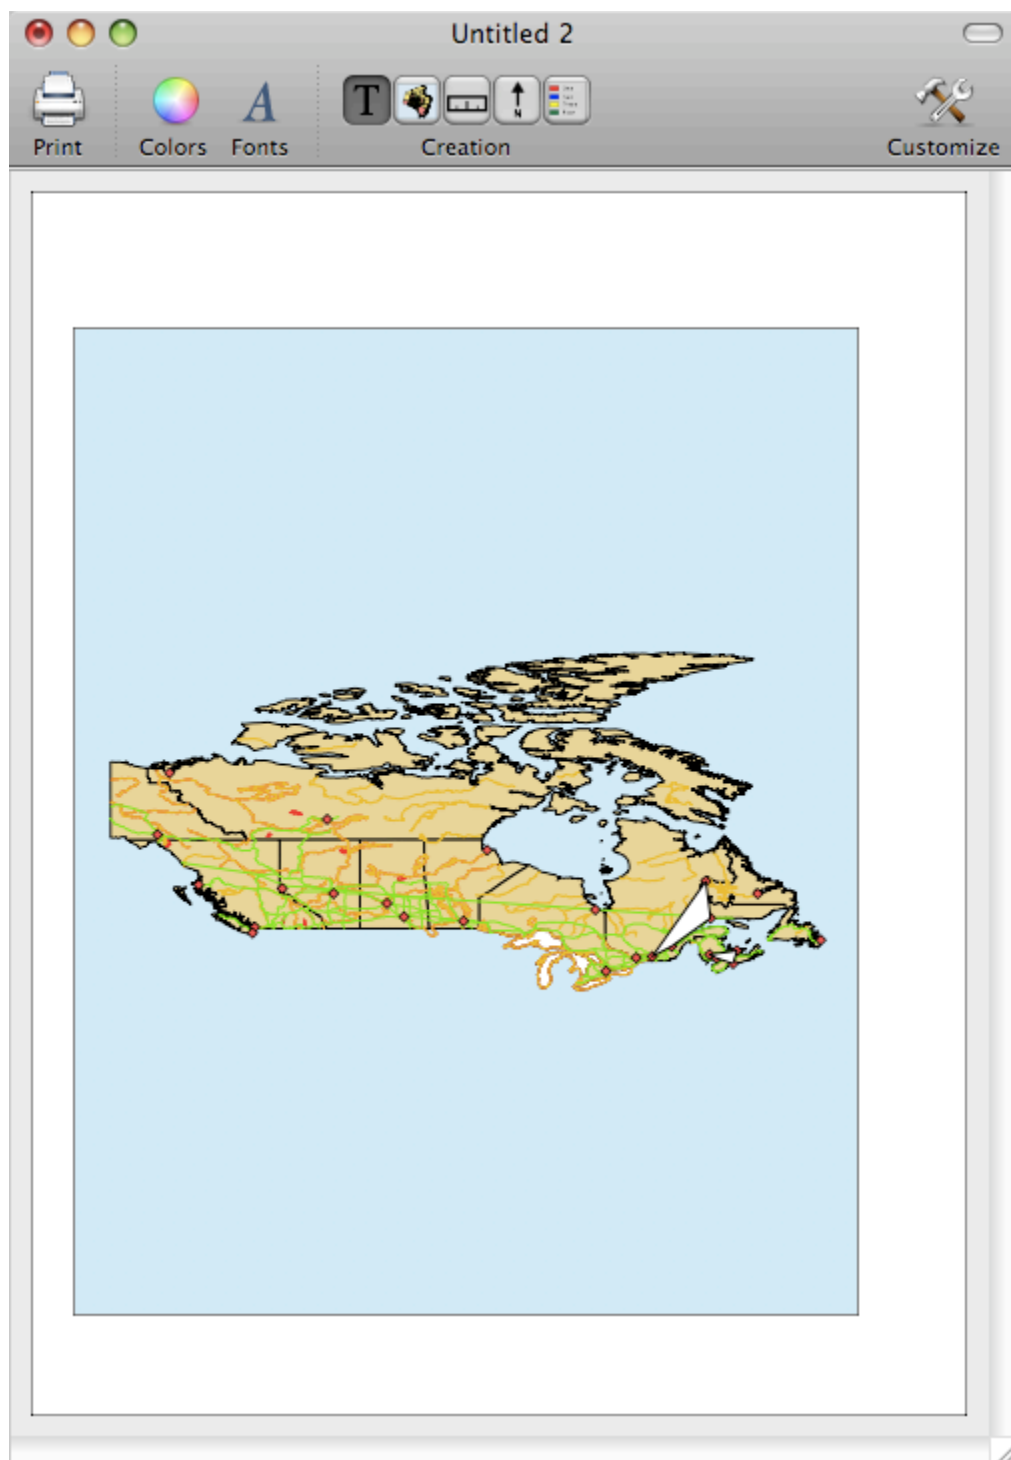

Map Layout Popoup

12.2.2 Placing a Map into the Map Layout Window

Place a map view into a Map Layout

 To add a map into a map layout, the map must already be saved to disk. If the map you are working on is not available (named Untitled), you will not be able to add it to the map layout.

1. Using the Add New Map toolbar icon ()
 drag a rectangle in the map layout window to the size you want the map to be and release.
 Choose **Insert Map** from the context menu
 The map appears in the window.
2. Adjust the size and location of the Map by clicking once on the Map to select it and then dragging it in the window.
 This is an example of a Map inserted into a map layout.

Map Layout With Inserted Map

Once a map is in place on the Map Layout, you may change the map set referred to by the map (and any associated legends and scales) by selecting the map and using the **Change Map** command from the contextual menu to retarget it to any map in a currently open Mapset Document.

You can add multiple maps to the same Map Layout page and they can refer to either the same or different Mapset documents. Scale, pan visible layers in these maps are independent of each other.

Layer visibility in maps in Map Layout documents are handled independently from the more dynamic Map Windows. Initially, visible layers in the Map Window are propagated to the Map Layout copy of the map. Although features are updated live (along with styles), the hidden state of layers is not updated.

12.2.3 Changing the visible Map area in Map Layout

Zoom and pan a map in a map layout

Cartographica Maps that are embedded in a Map Layout can be zoomed and panned independently.

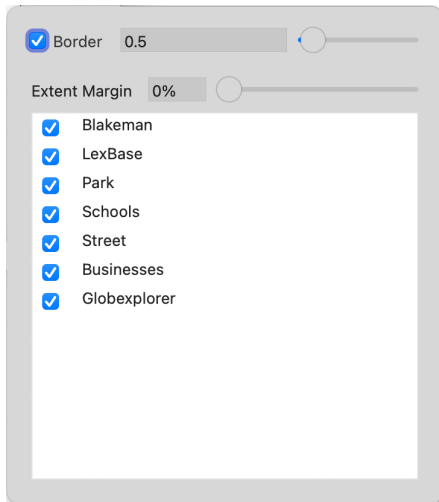

1. Click on the Map in the Map Layout window to select it.
This will cause the handles to appear around the map signifying that it is selected
2. Click again on the Map to make it active
The box surrounding the Map will become blue signifying that the Map is now in focus. At this point, many commands for navigating and controlling the Cartographica Map Window now become usable in this map.
3. To zoom the map, use the items in the **View** menu or use the Zoom Tool (choose **Map > Zoom Tool**) to zoom the map.
4. To pan the map, choose **Map > Pan Tool** and then drag inside of the Map to move

12.2.4 Including or excluding layers from a Map (from Map View Details...)

Choose displayed layers for a map inside of a map layout

Layer visibility in maps in Map Layout documents can be adjusted using the **Details...** popover.

1. Click on the Map in the Map Layout window to select it.
This will cause the handles to appear around the map signifying that it is selected
2. Control-click (or right-click) on the Map Layout window to bring up the context menu and select **Details...**
The **Details...** popover will come forward.
3. Click in the checkbox corresponding any layer that you want to make visible (checked) or invisible (unchecked).
This is an example of a **Details...** popover when displayed

Map Layout Map Details Popover

12.2.5 Including or excluding layers from a Map (from within the map view)

Choose displayed layers for a map inside of a map layout

Layer visibility in maps in the Map Layout documents can also be adjusted directly in the view. Initially, visible layers in the Map Window are propagated to the Map Layout copy of the map. Although features are updated live (along with styles), the hidden state of layers is not updated.

1. Click on the Map in the Map Layout window to select it.
This will cause the handles to appear around the map signifying that it is selected
2. Click again on the Map to make it active
The box surrounding the Map will become blue signifying that the Map is now in focus.
3. Use control-click (or right-click) to bring up the context menu and toggle each layer with the named entry. Layers which are visible in this particular Map are checked.

⚠ Map Layouts are designed for a single page, but that page may be of any size. Choose **File > Page Layout** to change the page size. Page size changes take effect immediately and provide a good way to target large-format printers.

12.3 Placing elements in the Map Layout

Once you have placed a map, you may place titles, scales, legends or compasses to further customize the appearance of the printed layout.

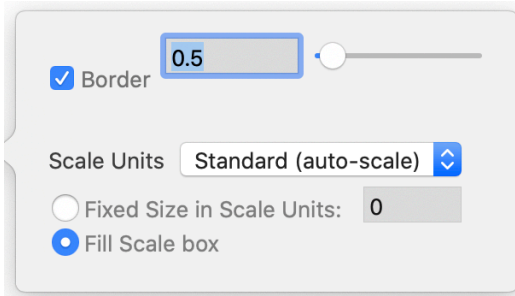

12.3.1 Adding a scale box to Map Layout

1. Do one of the following:

- From the Map Layout Toolbar, choose the New Scale Box toolbar icon ()
 - Choose **Add Scale** from the context menu.
2. Drag a rectangle in the map layout window to the size you want the Scale to be and release.
The scale box appears in the map layout window.

Customizing a scale box

1. Double-click the scale box
The Scale Box Options sheet will appear

Scale Box Options Sheet

2. Set **Scale Units** to one of the following:
 - Automatic
 - Standard (auto scale)
 - Metric (auto scale)
 - Or one of the measurements
3. Do one of the following:
 - Choose **Fixed Size in Scale Units** to set the length of the scale bar to a particular number of units
 - Choose **Fill Scale Box** to have Cartographica use whatever length comes closest to filling the scale box on the page

Default Units

Since 1.5.4, the Cartographica Preferences window contains preferences that control the units that are used as the default units for new Scale boxes (for both area and linear measurements). These preferences are used for *new* scale boxes.

Adding a legend to Map Layout

1. Do one of the following:
 - From the Map Layout Toolbar, choose the New Legend toolbar icon ()
 - Choose **Add Legend** from the context menu.
2. Drag a rectangle in the map layout window to the size you want the Legend to be and release.
The Legend box appears in the map layout window.

You can now position or resize the Legend as desired. When you place a legend, items are grouped together in a manner so as to use all the available space efficiently without becoming confusing. If there are multiple styles defined in a single style, they are grouped under the layer name, otherwise, the layer's style swatch appears to the left of the style.

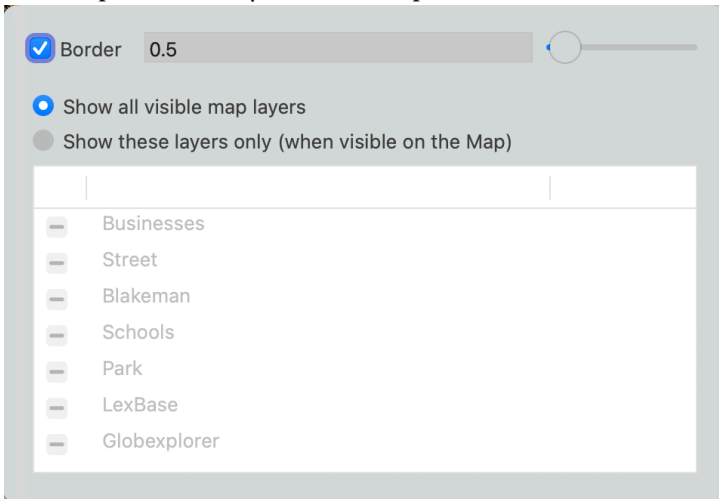

When there is insufficient space to display all features of the Legend, a yellow warning triangle shows up at the bottom of the rectangle to indicate that there is a drawing issue and that the box needs to be expanded.

- ⚠ For Legends in Map Layout (and in the pop-over **Legends** window, the title of each group is taken by the **Name** field in the style. If you want to change the name of a particular group, you can do so by changing that value.

12.3.2 Including or excluding layers from a Legend with Details...

Legends can contain any subset of available layers in their associated maps. Initially, all visible layers are added to the Legend when it is inserted in the Map Layout. This can be changed after the Legend is added from either the pop-up menu for the Legend, or from **Details...** popover in the pop-up.

1. Click on the Legend in the Map Layout window to select it.
This will cause the handles to appear around the map signifying that it is selected
2. Use control-click (or right-click) to bring up the context menu and choose **Details...**
This will present the Layout Details Popover

Map Layout Legends Details Popover

3. Select **Show all visible map layers** to show the legend for every visible layer in the associated Map (in the Map Layout document).
4. Select **Show these layers only (when visible on the Map)** to show the legend for the selected subset of layers.

- ⚠ Legends will only be shown for layers that are selected for display in the associated Map view, even if you have chosen the layer to be displayed in the legend manually.

12.3.3 Including or excluding layers from a Legend with menu

Legends can contain any subset of available layers in their associated maps. Initially, all visible layers are added to the Legend when it is inserted in the Map Layout. This can be changed after the Legend is added.

1. Click on the Legend in the Map Layout window to select it.
This will cause the handles to appear around the map signifying that it is selected
2. Use control-click (or right-click) to bring up the context menu and toggle each layer with the named entry. Layers which are visible in this particular Map are checked.
3. To synchronize with the current visible layers in the associated Map (in the Map Layout document), choose **Synchronize with Map** from the context menu.

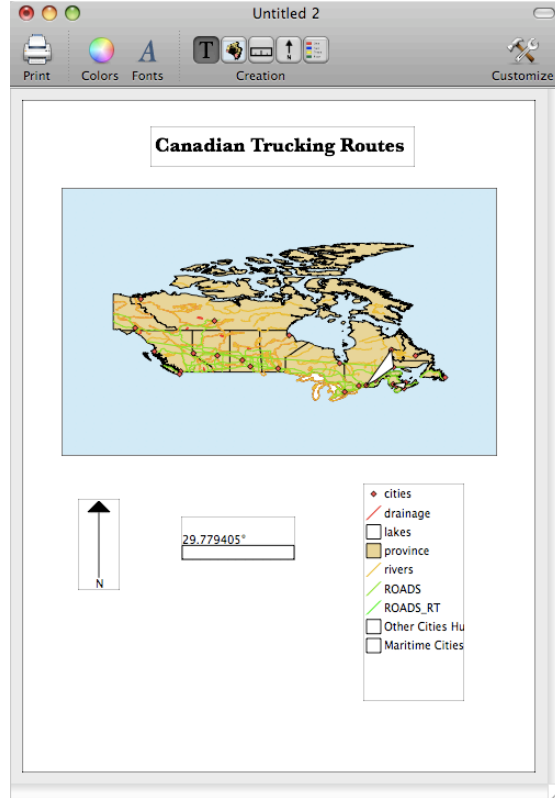

Adding a compass to Map Layout

1. Do one of the following:
 - From the Map Layout Toolbar, choose the New Compass toolbar icon ()
 - Choose **Add Compass** from the context menu.
2. Drag a rectangle in the map layout window to the size you want the Compass to be and release.
The Compass box appears in the map layout window.

12.3.4 Adding a Text to Map Layout

1. Do one of the following:
 - From the Map Layout Toolbar, choose the New Text Box toolbar icon ()
 - Choose **New Text Box** from the context menu.
2. Drag a rectangle in the map layout window to the size you want the Text Box to be and release.
The Text box appears in the map layout window.
3. You can now position or resize the Text Box as desired.
To change the fonts used in Scale, Legend, and Text items, select the item and then use the Macintosh Font Panel (choose **Edit > Show Fonts**) to change the text attributes.

Here is an example of a Map Layout window with all of these elements added:

Scale, Legend, and Text Box added into map layout

When a map is selected (or one of its related layout features, such as the scale or legend), then all related layout features are badged with a blue dot to indicate that they are related. When not selected, the blue dot disappears.

To move items in the Map Layout, click once on the item to select it (you should see "handles" in each of the corners and along the edges), and then drag the item to its desired location.

To resize any of the items in the Map Layout, click once on the item to select it and then drag one of the handles to change the size of the item.

Map Layout items associated with a given Map will show an indicator in the lower-left-hand corner of the item in order to represent the connection between these items. Thus, if you click on a Scale for a Map that also has a Legend, all three items will be "badged" as being related to each other.

Some Map Layout items have yellow warning triangles () when there is something wrong with the visual presentation. For example, Legends may have this indicator when there is not enough room in the item to show the entire legend. To fix this, either remove items from the legend, change the font, or resize the legend box.

12.3.5 Removing Map Layout objects

1. Select the object you wish to delete
2. Choose **Edit > Delete**.

13 Column Formulas

13.1 Introduction to Formulas

Cartographica supports formulas in columns, providing a way to compute new values from existing columns or from geometric attributes of the feature for which the column is being calculated. The formula interpreter uses an embedded python interpreter with the basic functions plus the math library imported at the base. This chapter lists the functions and constants available.

Cartographica uses an embedded Python 3 interpreter to interpret the formulas, or "expressions" that make up the Column Formulas. This provides an enormous amount of flexibility in these expressions and although we detail the key aspects of python expressions, basically anything that can be executed as a python expression is fair game in a Column Formula in Cartographica.

The simplest expression is just a replacement value. Although it's not the best use of processing power, it is an effective way to put a constant value in a column as a placeholder.

The most common use of Column Formulas is to create a new value based on the values of another column or columns in Cartographica. To create these simple relationships, use standard arithmetic operators (below) to combine fields.

For example, a population column and an area column can be combined to determine density.

```
POPULATION / AREA
```

Another use of Column Formulas is to create new columns by splitting data that has been encoded into a string. For example: a column named CITYSTATE containing 'Washington, DC' may be appropriate for an address line, but may not be appropriate for your needs, so you could use

```
CITYSTATE.split(',')[0].strip()
```

to grab the city and

```
CITYSTATE.split(',')[1].strip()
```

to grab the state from the CITYSTATE column. Breaking this down, the `split` method splits a string into an array of substrings that were previously separated by the character in quotes (','), then that array is dereferenced to it's 2nd element (python's understanding of the world is based on the 0 being the first position) and then that string has the `strip` method run against it, which removes spaces from the start and end of the string. Thus, you get the state.

Or if you had a column BLOCKGROUP containing a block group identifier "210670001001" and wanted to pull out the FIPS State and county code from it, you could use:

```
BLOCKGROUP[0:5]
```

(pulling the first 5 characters, starting at position 0 from the text string).

Version 1.5 Change

Versions of Cartographica prior to Version 1.5 used the built-in Python 2.7 interpreter on macOS to interpret functions. In versions, 1.5 and later, a version 3.8+ interpreter is used. For most uses in Cartographica, this does not change the behavior, however string functions are now mostly methods on string objects (as shown in the CITYSTATE example above), and thus must be called on the text string objects, as opposed to called directly.

Cartographica will attempt to warn you when you have an old-form function in use, so that you may change it to the new method-based invocation.

Fortunately, the 1.5 methods are compatible with 1.4.x, so you can safely change the formulas and save them for MapSets that are in use by both.

13.1.1 Creating a Column Formula

1. Select the layer in which you want to create a formula in the layer stack
2. Choose **Window > Show Layer Info** to bring up the **Layer Info** window.
3. To create a new column in the layer do one of the following:
 - click on the + button or choose
 - **Layer > Add Column**
4. Click on the new column name and change its name to something meaningful
5. Click the **Set Formula...** button to bring up the formula sheet

Compute AREALAND from:

BLACKS BLKGRP FAMPOV FHH FIPSSTCO GROUP HOUSE1 HOUSE2
HU100 ID INCOME MALES MERGE NAME OWNER POP1 POP100
POP2 PUBASSIS SAMEHOUS SHAPE_area SHAPE_len TRACT_1
UNEMPLOY VACANT

⚙️ ▼ Cancel OK

Formula Sheet

6. Drag a column name from the bottom pane to add a reference to another column to this formula. Colors of the column names denote the type of data.
7. Now add the rest of the formula by typing in the formula area and dragging other column references to it.
8. When you are done, click OK to set the formula

While you enter the formula, Cartographica is constantly evaluating it looking for potential problems and providing you guidance in how to solve those problems. Unfortunately, there are some errors for which Cartographica cannot determine the problem and can only tell you that the result would be invalid.

For other cases, consult the Expression Warnings table for meanings and suggested solutions to problems detected by Cartographica.

Warning Message	Meaning
No result value for test data	This expression results in no value. Generally this is the result of calling a function that doesn't return a value
Math error-some fields may be wrong/missing	This expression evaluates to an arithmetic error using the test data. This warning indicates that under some circumstances (possibly all), field values will not be set. A common cause of this is an expression that results in infinity or attempts to divide by zero using the test data.
Syntax error in formula	This expression is invalid. This is often displayed during typing due to issues such as missing parenthesis, missing operators and other errors.
Interpreter exception	This expression is invalid in a way that we cannot determine.

Warning Message	Meaning
Geometries can't be stored in columns	The result of the expression will be a geometry. The most common cause of this is a missing final expression when evaluating a centroid or other geometric value.
Unknown type	The result of this expression will be an unknown type. Because of this, no data will be stored in the resultant column. Check that any functions used in the expression don't return complex types, such as geometries
Unknown attribute	The result of this expression references an attribute (using dot notation) that is not known to the interpreter. Check the spelling of anything after a dot.
Unknown symbol:	The referenced symbol is unknown to the interpreter. This is generally caused either by putting two column references next to each other without an operator or by a typo
Wrong geometry type	A function in this expression that works on a geometry is being used with the wrong type of geometry. For example: you are trying to take the area of a point.
Other geometry error	The expression uses some geometry function incorrectly, resulting in confusion for the geometry processor
Can't initialize interpreter	Internal error, please report to ClueTrust

Expression Warnings

- ❗ Cartographica does not resolve circular references or directional references. Each column is executed in column order when they are loaded and are updated when they are changed. As such, if you have a Column Formula that is dependent on another Column Formula, you may experience unexpected results.
To refresh an individual value, just set the formula again.

13.2 Conditional Expressions

Cartographica supports conditional expressions to provide for complex calculations, such as discontinuous functions. These functions may be nested, so that decision trees can be implemented with great flexibility.

The format for conditional expressions is:

```
true_expression if condition else false_expression
```

In this case, the expressions can be any other expression, including a nested conditional expression, so it is possible to create a conditional expression of arbitrary complexity by chaining them together.

 Parenthesis around the condition are optional but are useful for clarification.

For example, if you were to need a function that takes a number and rounds to the nearest 500 in the case that the number is positive, but clamps to zero in the case the number is negative, you could write it like this:

```
trunc(VALUE/500)*500 if (VALUE>0) else 0
```

This would result in a value of 0 for all values <500, 500 for all values between 500 and 1000, 1000 for all values between 1000 and 1500, etc.

13.3 Mathematical functions

Function	Result
int int (any value)	This function converts between any data type and an integer value.
float float (any value)	This function converts between any data type and an floating piont value.
float ceil (float x)	Returns the ceiling of the x as a float, the smallest integer values greater than or equal to x.
float copysign (float x, float y)	Returns x with the sign of y. <code>copysign(2,-1)</code> returns -2.
float fabs (float x)	Returns the absolute value of x
int factorial (int x)	Returns x factorial. Fails if x is not an integer or is negative.
float floor (float x)	Returns the largest integer value less than or equal to x.

Function	Result
float fmod (float x, float y)	Returns x modulus y.
float[2] frexp (float x)	Returns x with the mantissa and the exponent as separate components of a pair m,e), such that $x = m * 2^e$. To use one or the other, you must refer to them as a subscript, thus [0] for the mantissa and [1] as the exponent.
float fsum ([any value]...)	Returns the sum of all values in the list.
bool isinf (float x)	Returns True if x is infinte, False otherwise.
bool isnan (float x)	Returns True if x is the IEEE NAN value, False otherwise.
float ldexp (float x, int i)	Returns $x * 2^i$
float modf (float x)	Returns the fractional and integer parts of x as a pair (f,i) such that $x=f+i$. To use the individual components, they must be accessed by subscript, thus [0] for the fraction and [1] for the integer.
float trunc (float x)	Returns x truncated.
float exp (float x)	Returns e^x
float log (float x[, float base])	Returns the natural logarithm of x if there is only one parameter. Returns the logarithm of x given base, calculated as $\frac{\log(x)}{\log(base)}$.
float log1p (float x)	Returns the natural logarithm of 1+x (base e)

Function	Result
float log10 (float x)	Returns the base-10 logarithm of x. Generally more accurate than log(x,10)
float sqrt (float x)	Returns the square root of x.
float pow (float x, float y)	Returns x^y

13.4 Trigonometric Functions

Function	Result
float acos (float x)	Returns the arc cosine of x, in radians
float asin (float x)	Returns the arc sine of x, in radians.
float atan (float x)	Returns the arc tangent of x, in radians.
float atan2 (float y, float x)	Returns the arc tangent of $\frac{x}{y}$ in radians. The result is between -pi and pi. Differs from just using $\text{arc}(\frac{x}{y})$ because it can use the sign of each number to determine which quadrant to put the result in.
float cos (float x)	Returns the cosine x radians.
float hypot (float x, float y)	Return the Euclidean norm, $\sqrt{xx + yy}$. This is the length of the vector from the origin to point (x,y).
float sin (float x)	Returns the sine x radians.

Function	Result
float tan (float x)	Returns the tangent x radians.
float degrees (float x)	Converts the angle x from radians to degrees.
float radians (float x)	Converts the angle x from degrees to radians.
float acosh (float x)	Returns the inverse hyperbolic cosine of x.
float asinh (float x)	Returns the inverse hyperbolic sine of x.
float atanh (float x)	Returns the inverse hyperbolic tangent of x.
float cosh (float x)	Returns the hyperbolic cosine of x.
float sinh (float x)	Returns the hyperbolic sine of x.
float tanh (float x)	Returns the hyperbolic tangent of x.

13.5 Mathematical Constants

These constants are available for use in formulas in Cartographica:

Constant	Value
pi	The mathematical constant pi.
e	The mathematical constant e.

13.6 Geometric Functions

These geometric functions are available for use in formulas in Cartographica. To use them, you must always specify `geometry.function(parameters)`. For example, to obtain the area of the current geometry (valid only for polygons), you would use `"geometry.area()"`.

Some of the geometric functions return special object types (Rect and Point) that must be further operated upon in order to export the values.

Point objects consist of an x and y coordinate, which are accessed by appending `".x"` or `".y"` respectively to the function result. For example, `"geometry.centroid().x"` and `"geometry.centroid().y"`.

Rect objects consist of the x and y origin and the width and height, which are accessed by appending `".x"`, `".y"`, `".width"`, or `".height"` respectively to the function result.

Each of the geometric functions can return their values in the CRS for the map (default) or the CRS for the geometry's layer (set `'layerCRS'` to 1).

float geometry.area (<i>[bool layerCRS]</i>)	<p>Returns the area in the current coordinate system units, using either the map coordinates (<code>layerCRS</code> is 0 or not present) or the original layer coordinates (<code>layerCRS</code> is 1).</p> <div>⚠ This function is only available for polygons.</div>
float geometry.length (<i>[bool layerCRS]</i>)	<p>Returns the length in the current coordinate system units, using either the map coordinates (<code>layerCRS</code> is 0 or not present) or the original layer coordinates (<code>layerCRS</code> is 1).</p> <div>⚠ This function is only available for polygons and lines</div>
Rect geometry.bbox (<i>[bool layerCRS]</i>)	<p>Returns the Rect of the bounding box of the current geometry using either the map coordinates (<code>layerCRS</code> is 0 or not present) or the original layer coordinates (<code>layerCRS</code> is 1).</p> <p>The return value is a structure containing <code>x</code>, <code>y</code>, <code>width</code>, and <code>height</code>. To access each individual element, use the dot notation: <code>geometry.bbox().x</code> to retrieve the x coordinate, for example.</p>
Point geometry.midpoint (<i>[bool layerCRS]</i>)	<p>Returns the Point representing the midpoint of the line in the current coordinate system, using either the map coordinates (<code>layerCRS</code> is 0 or not present) or the original layer coordinates (<code>layerCRS</code> is 1).</p>

	 This function is only available for lines.
Point geometry.centroid (<i>[bool layerCRS]</i>)	<p>Returns the Point representing the centroid of the feature in the current coordinate system, using either the map coordinates (<i>layerCRS</i> is 0 or not present) or the original layer coordinates (<i>layerCRS</i> is 1).</p>  This function is only for points, multipoints, and polygons.

13.7 Text Functions

The following text functions are available for use in formulas in Cartographica. To use them, they must always be "attached" to a string object, as they are string object methods, as opposed to pure functions. Therefore, if you have a string column named `my_value`, you must use `my_value.upper()` to convert this to upper case. The length function, `len(my_value)`, is a generic function and thus still must surround the string variable.

Also note that strings use collection operators as well, so if you want the first 2 characters of a string, you may retrieve them by using `my_value[0:2]`; similarly, the 3rd and 4th characters may be retrieved by using `my_value[2:4]`. In addition, negative numbers connote references from the end of the string, so `my_value[-2:]` would retrieve the last 2 characters at the end of the string (the lack of a number after the colon connotes until the end).

1.5 Change

For those who have used Text functions in the past, there was a change in version 1.5 and beyond because of the adoption of a new Python 3-based back-end. In Cartographica 1.5 and beyond, Text functions are object methods and not pure functions. This means that if you previously used "upper(my_value)" to convert `my_value` to uppercase, then you now must use "my_value.upper()". Cartographica will present an error or warning if this change affects existing formulas.

<code>str.capitalize()</code>	Returns text in title case. First letters of words are made upper case, with the remainder lower.
<code>str.upper()</code>	Returns text in upper case.
<code>str.lower()</code>	Returns text in lower case.

<code>int .find(str sub[, int start[, int end]])</code>	Returns the location that the string sub is found within the string (starting at the beginning). Optional parameters are start and end, the starting and ending locations of the search.
<code>int .rfind(str sub[, int start[, int end]])</code>	Returns the location that the string sub is found within the string, starting at the end. Optional parameters are start and end, the starting and ending locations of the search.
<code>int .count(str sub[, int start[, int end]])</code>	Returns the count of the number of times that the string sub is found within the string. Optional parameters are start and end, the starting and ending locations of the search.
<code>[str] .split([str sep], [int maxsplit])</code>	<p>Returns an array of text strings that are separated by the text string sep, optionally with a maximum number of splits, maxsplit. If the separator (sep) is omitted, the algorithm will use consecutive whitespace as the split.</p> <p><code>'1,2,3,4'.split(',')</code> returns <code>['1','2','3','4']</code></p> <p>This method is especially useful for creating new columns out of columns that may have been strings with multiple values previously. For example, let's say you have a column for the City, State of an address named CITYSTATE and containing "Washington, DC" for example. By creating two new columns and using these formulas respectively:</p> <p>City: <code>CITYSTATE.split(',')[0].trim()</code></p> <p>State: <code>CITYSTATE.split(',')[1].trim()</code></p> <p>you will get the City in one column and the State in the next. Note that we use the 1st array element for the first and the 2nd array element for the second, since array elements start with 0, not 1.</p>
<code>str .join([str])</code>	<p>Returns a new string created by joining the elements of the string array by the string that the method is executing on. This can be used in interesting ways to join values from other columns. For example, given columns A, B, C and D, you can join them by hyphens by doing the following:</p> <p><code>'-'.join([A,B,C,D])</code></p> <p>Note: in the above, we created an ad hoc array by putting the individual values between square brackets and separated by commas.</p>
<code>str .strip([str stripchars])</code>	Returns a new text string with the trailing and leading whitespace removed. If you pass a string in stripchars, the method will remove those characters (instead of whitespace) from the leading and trailing positions.

<code>str.rstrip([str stripchars])</code>	Returns a new text string with the trailing whitespace removed. If you pass a string in <code>stripchars</code> , the method will remove those characters (instead of whitespace) from the trailing positions.
<code>str.lstrip([str stripchars])</code>	Returns a new text string with the leading whitespace removed. If you pass a string in <code>stripchars</code> , the method will remove those characters (instead of whitespace) from the leading positions.

13.8 Date Functions

Although Cartographica isn't awash in great date functionality, mostly owing to the lack of solid date, time, and timezone support in many geospatial data formats, its Column Formulas do have access to the date functionality of Python, which means there are some sophisticated date capabilities available.

13.8.1 Use of date classes

Most of the date and time functions work on `datetime` objects, which are not usable by Cartographica directly. However, they can be further operated on to retrieve the data stored within them by using day, month, year (and hour, minute, second) accessors. For example `datetime.today().day` will provide the integer day of the month.

Dates can also be converted into strings by using the `strftime()` method on a `datetime` object. For example, `datetime.today().strftime("%Y-%m-%d")` will provide the current date in "YYYY-MM-DD" form, or 2020-01-23 if it were the date this page was being written.

<code>datetime.datetime.today()</code>	Today's date as a <code>datetime</code> object
<code>datetime.datetime.utcnow()</code>	Today's date and time in UTC as a <code>datetime</code> object
<code>str.strftime(str format)</code>	String representation of the requested date
<code>int.weekday()</code>	Return the day of the week as an integer (0=Sunday, 1=Monday, etc.)
<code>str.ctime()</code>	Return the date and time as a string in human-readable format.
<code>datetime.strptime(str date_string, str format)</code>	Create a new <code>datetime</code> object from the <code>date_string</code> using the requested format.

13.8.2 Date Format Strings

The Python documentation details the [date format](#), however the strings used for `strftime` and `strptime` are built from the following directives:

Directive	Meaning	Example
%d	Day of the month as a zero-padded decimal number	01, 02, ..., 31
%m	Month of the year as a zero-padded number	01, 02, ..., 12
%y	2-digit year as a zero-padded number	00, 01, ... 99
%Y	4-digit year as a zero-padded number	0000, ..., 2020, ..., 9999
%H	24-hour clock Hour as a zero-padded number	00, 01, ..., 23
%I	12-hour clock Hour as a zero-padded number	00, 01, ..., 12
%p	AM/PM (or local equivalent)	AM, PM
%M	Minute as a zero-padded number	00, 01, ..., 59
%S	Second as a zero-padded number	00, 01, ..., 59

Common Examples

String	Output Example
%Y-%m-%d	2019-12-31
%H:%M:%S	23:59:59
%m/%d/%y %H:%M:%S	12/31/19 23:59:59

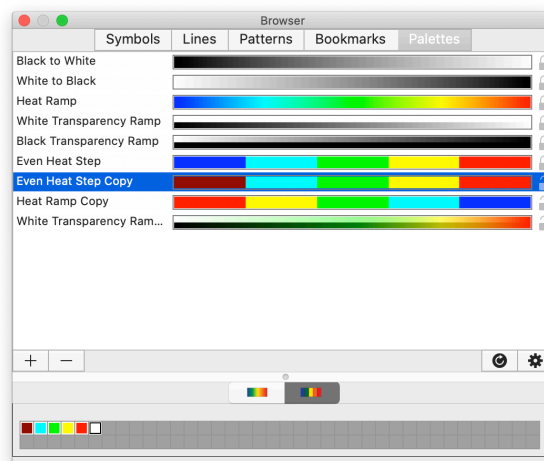

14 Color Palettes

Color Palettes are groups of colors that are put together to achieve some specific effect. For ramps (continuous color) the colors show a smooth transition across a range of values, highlighting fast rates of change. For segments (discontinuous color) the colors represent individual classes of information.

Cartographica has a sophisticated palette management system which provides tools to create, modify, import, and use color palettes in any part of the program that uses color.

Colors may be dragged from almost any source and Cartographica will import palettes from the ColorBrewer site (or anything that exports in a similar format).

Palette management is done through the Palettes tab of the Uber Browser, which provides editing and previewing capabilities.

UberBrowser with Palettes

The palette tab is composed of two primary sections. The Palette List at the top of the window, which shows all available palettes that you have access to. The Palette Inspector at the bottom provides the tools to view the particulars of the palettes and make changes to them.

The Palette List shows the name and preview of each palette and a locked symbol if the palette is not editable.

The Palette Inspector shows the colors in the selected palette and whether the palette is Continuous (Cartographica interpolates out the colors in between) or Segmented (the colors are repeated in between).

To learn how to use palettes with vector and raster layers, see [Styling Vector Layers](#) and [Styling Raster Layers](#)

14.1 Create a new palette

1. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
2. Click the Add (+) button to add a new palette.
A single color palette will be added to the bottom of the list.
Since the new palette is selected, the Palette Inspector shows the current colors in the palette and the Continuous button is selected.
3. Click on the name column and enter a new name for the new palette.
4. Click in the single gray-outlined box to add a new color to the palette.
Always click here to add a color to the end of the palette

14.2 Removing a palette

1. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
2. Click on the palette you wish to remove

 Palettes with the lock symbol next to them will not be editable or removable

3. Click on the Remove(-) button

Color Picker

14.3 Changing a color in a palette

1. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
2. Click on the palette in the Palette List to select it
The colors of the palette will now be in the Palette Inspector
3. Click on the color once to select it
If the Color Picker is already up, the color will appear in it ready to be changed at this point
4. Click on the color a second time to bring up the Color Picker
5. Change the color using the color picker and the palette will change in unison.

Switching between ramp and segmented palettes

1. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
2. Click on the palette in the Palette List to select it
The colors of the palette will now be in the Palette Inspector
3. At the top of the Palette Inspector, click on the Continuous button (left) to change to a ramp color palette or on the Segmented (right) to change the interpolation method.

Reversing the colors in a palette

1. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
2. Click on the palette in the Palette List to select it
The colors of the palette will now be in the Palette Inspector
3. In the Palette Inspector, click on the reversal button to change the order of the colors.

Pasting a color brewer palette

[ColorBrewer](#) is a well-known resource for creating meaningful palettes for maps. Cartographica can accept palettes directly from the ColorBrewer site for use in the Palettes tab of the Uber Browser. Although we specifically point at ColorBrewer for good palettes, Cartographica can import Javascript-style CSS colors (hex,RGB,HSL) or a list of numbers where the Red, Green, and Blue components are separated by commas and have a range of 0-255 and where colors are separated by semicolons.

```
229, 245, 249; 153, 216, 201; 44, 162, 95;
```

or

```
['#e5f5f9', '#99d8c9', '#2ca25f']
```

1. Visit the [ColorBrewer](#) site to compose your palette
2. When you are done creating your palette, click **Export Your Colors** to bring in the export window
3. Copy the numbers in the box or **just copy-n-paste**
4. Switch back to Cartographica
5. Choose **Window > Show Uber Browser** and click the **Palettes** tab to bring up the Palettes Tab of the Uber Browser.
6. Choose **Edit > Paste** to past the palette into your Palette Window
7. Rename the color palette by clicking on the name and typing a new one.

15 AppleScript Scripting

Learn how to use AppleScript to control Cartographica

Cartographica supports scripting through AppleScript in order to control the program and add customize it for the functionality that your particular application needs. Support for scripting in Cartographica is extensive and it can be used to add, modify and delete Layers, Features, Columns and data related thereto.

Beyond support for basic data editing, Cartographica also provides scripting support for many of the built-in commands that are available for analysis.

15.1 Scripting Architecture

The Cartographica scripting architecture uses a standard AppleScript paradigm which can be used by any OSA (Open Scripting Architecture) compliant language to control and augment the application.

The primary object in Cartographica is a Document. Structured just like the Cartographica Mapset Document, the Document object contains a list of Layers. These Layers, in turn, contain various properties and a list of Features just like in Cartographica's MapSet Document.

15.2 AppleScript Vocabulary

As is standard for AppleScript, the full description of the vocabulary is contained in the Application itself and visible to the standard AppleScript Editor (found in the Utilities folder inside of the Applications folder). We have summarized the main objects and their use in [AppleScript Main Objects](#).

Map Document	Cartographica MapSet Document
Map Layout Document	Cartographica Map Layout Document
Map Window	Window containing a MapSet Document
Map Layout Window	Window containing a Map Layout Document
Map Viewer	A component of a Map Window that shows the map
Layer	Layer in a Cartographica Document, used to store Features and dictate what they mean and how they are presented.

Feature	Feature in a Layer, used to store Geometry and Field Data for individual features.
Schema	An attribute of a Layer, used to store the Columns and information about the columns.
Style	An attribute of a Layer, the Style describes how the features in a layer are presented. Used to store Style Parameters.
Style Parameter	An attribute of a Style, the Style Parameter describes how a particular class of Features that are displayed using a Style are displayed.
Geometry	An attribute of a Feature, Geometry stores the geometric attributes of a Feature. Made up of 1 or more parts, which in turn are made up of geopoints.
Coordinate Reference System	Coordinate Reference Systems (sometimes referred to in Cartographica and elsewhere as just projections). Global objects that can be assigned to layers and Maps.
Column	Contained in a Schema, each Column describes a particular kind of data that is a part of the Feature's definition within a Layer. The Column contains the type, length and other attributes.
Field Data	Field Data are contained by a Feature and describe the values for a particular Column as it pertains to that Feature.
Field Mapper	Field Mappers are used to map fields between layers for certain analysis operations. They are made up of field maps, which

AppleScript Main Objects

15.2.1 Visibility into the current Map Window

Versions of Cartographica prior to 1.4 could not interact with the visible map. Although this was not an enormous problem, it did result in complications when trying to operate on a subset of layers or features when performing scripted operations. In 1.4, Cartographica now exposes the Map Viewer, which in turn exposes the selections in the layer stack and the map/data view, thus allowing you to write scripts that work on the selected layers or features.

15.3 Example Scripts

This section contains some simple examples of what can be done with AppleScript scripting and Cartographica.

Setting a column value for all Features in a Layer

```
tell application "Cartographica"
    set targetlayer to layer "Businesses" of the first document
    repeat with aFeature in every feature of targetlayer
        set value of field data "Copyright" of aFeature to "© 2020, ClueTrust"
    end repeat
end tell
```

The example above demonstrates cycling through every feature in the targetLayer (in this case a layer with the name "Businesses") and setting a value of the data field named "Copyright" to — © 2020, *ClueTrust*.

There are further example scripts on the [ClueTrust Support site](#) if you search for AppleScript.
